32 The majority of the most common hemoglobinopathies, which include sickle cell disease
33 (SCD) and thalassemia, are not indigenous to Europe but are now becoming prevalent. In
34 this issue, Cela et al (1) report on the first Spanish National Registry of Hemoglobinopathy,
35 which provides an opportunity to recognize and address this increasing prevalence. The
36 authors report important epidemiological and public health outcome data from 715 eligible
37 patients. Barely 15 years following the first report of a case of SCD in Spain, the average
38 number of new cases has risen from 1.7 per year before 1996, to 42.2 cases per year in the
39 5-year period between 2006 and 2010, while those for thalassemia remain relatively
40 unchanged (0.3 and 3.3, respectively). This reflects the pattern of migration to Spain mainly
41 from African countries. The main European Union migrant population groups come from
42 areas with a high prevalence of hemoglobinopathies (countries in the Middle East, North
43 Africa and Sub-Saharan Africa). However, Italy and Spain receive mainly African immigrants
44 due to their geographic proximity, while Greece and Central European countries receive
45 more patients from the Middle East Region (Figure 1).

46

47 A survey of the European Union reported that areas of low incidence such as Sweden and
48 Spain, have very low awareness of hemoglobinopathies and this leads to under-diagnosis
49 and lack of access to care for ethnic minority populations (2). Only a few countries – Cyprus,
50 UK, Belgium, Italy, France and Greece – have national or targeted education campaigns to
51 raise awareness about hemoglobinopathies. However, with current trends in migration this
52 situation may change, and historically low prevalence regions will now need to care for
53 increased number of patients with major hemoglobinopathies. Therefore urgent action may
54 be required within a short time to meet the challenges and address the opportunities.

55

56 Similar trends in the pattern of hemoglobinopathies were reported in Canada a generation
57 ago, with a fall in the British population from 60% in 1871 to 45% in 1971, and an increase in
58 French Canadians from 10 to 30%, leading to a rise in thalassemia prevalence (3).
59 Furthermore a report from the UK (4) showed a decrease in utilization of prenatal diagnosis
60 by migrants from Cyprus, and an increase among those from Pakistan and Sub-Saharan
61 African countries. The current report of a comprehensive National Hemoglobinopathy
62 Registry in Spain provides further evidence for the need to implement nationwide collection
63 of data in hemoglobinopathies.

64

65 The benefits of establishing registries have been recognized in many countries. As stated by
66 Hullahan et al (5) "a comprehensive understanding of the impact of hemoglobinopathies in
67 the USA is important to public health practitioners, researchers, health insurers, and policy
68 makers." In the United Kingdom (UK), the earliest registries for SCD and thalassemia were
69 developed independently (6, 7). Following the implementation of universal newborn and
70 linked antenatal screening for hemoglobinopathies in 2004, it became apparent that a full
71 comprehensive national hemoglobinopathy registry in the UK for both SCD and thalassemia

72 was imperative (8). In 2009, the National Hemoglobinopathy Registry was implemented and
73 by 2013-14 the majority of patient in England had been registered

74 (http://www.nhr.nhs.uk/wp-content/uploads/2015/10/NHR_AnnualReport_2014.pdf). A
75 national steering committee made of a multidisciplinary team is responsible for reviewing the
76 content and governance structure of this registry. This effort is led by the UK Forum on
77 hemoglobin disorders (<http://www.haemoglobin.org.uk/>) and two patient user groups: Sickle
78 Cell Society (<http://sicklecellsociety.org/>) and UK thalassemia Society (<http://www.ukts.org/>),
79 which raise awareness and resources to provide detailed patient information, treatment and
80 newborn outcomes.

81

82 National hemoglobinopathy registries across Europe will enhance monitoring of changing
83 demographics, service delivery and patient outcomes. In order to achieve comprehensive
84 coverage, it is necessary to consider innovative ways to increase patient registration and
85 accrual into the databases such as inclusion of:

- 86 i) Hospital medical records to synchronize with registry data and become a source to
87 update patient management and outcomes;
- 88 ii) Population demographics to include details about ethnicity and heritage, which may
89 be utilized to establish the target population for screening and intensive
90 enlightenment through their community organizations and social network;
- 91 iii) Insurance data that could also enhance national registries.

92

93 Appropriate funding of registries is a challenge that can be surmounted only through
94 effective advocacy and engagement of commissioning organizations. The fact that registries
95 may cost only a fraction of patient care should be an incentive for those commissioning
96 services and could enable the development of services for patients in affected communities.

97

98 The role of surveillance systems for hemoglobinopathies, such as registries, is significant for
99 the allocation of resources and public engagement and the data may facilitate policy making
100 decisions. By providing an overview of the demographic pattern of hemoglobinopathies, they
101 are essential tools for monitoring patient outcomes. As stated by Cela et al and others, they
102 also provide an important resource for research. It is reassuring to note the cost of running a
103 registry is affordable (7), and offers a resource for economic planning for equitable care and
104 service improvement. The development of national registries needs to be supported by rare
105 anemia networks such as the pilot European Network on Rare and Congenital Anemias-
106 ENERCA, or the recently established European Network- EuroBloodNet in order to foster
107 lessons from countries with advanced programmes. Non-European countries, such as those
108 in the Middle East and Sub-Saharan Africa, where the vast majority of patients live, may

109 benefit from such examples of good practice in order to utilize their limited resources
110 appropriately (9,10). In the long term, we should adopt an approach capable of facilitating
111 effective collaborations and sharing good practices between countries of high prevalence but
112 low in resources and those with lower prevalence but well-developed pathways of care.

113

114 **Conflicts of Interest:** Both Dr Baba Inusa and Dr Raffaella Colombatti confirm that they
115 have no conflicts to declare
