DETAILED CONTENTS

<i>Chapter 1</i>	Introduction	1
	Surveys of Secondary School Students	1
	Surveys of College Students and Young Adults Generally	1
	Content Areas Covered in This Report	2
	Purposes and Rationale for This Research	3
 <i>Chapter 2</i>	 Overview of Key Findings	 5
	Trends in Illicit Drug Use	11
	College-Noncollege Differences	16
	Male-Female Differences	17
	Trends in Alcohol Use	17
	College-Noncollege Differences	18
	Male-Female Differences	19
	Trends in Cigarette Smoking	19
	Age and Cohort-Related Differences	20
	College-Noncollege Differences	20
	Male-Female Differences	20
	Racial/Ethnic Comparisons	21
	Drug Use in Eighth Grade	22
	Summary and Conclusions	23
 <i>Chapter 3</i>	 Study Design and Procedures	 27
	Research Design and Procedures for the Surveys of Seniors	27
	The Population Under Study	27
	The Omission of Dropouts	27
	Sampling Procedures	29
	Questionnaire Administration	29
	Questionnaire Format	29
	Research Design and Procedures for the Surveys of Lower Grades	31
	Research Design and Procedures for the Follow-Up Surveys of Seniors	31
	Follow-Up Procedures	32
	Panel Retention Rates	32
	Corrections for Panel Attrition	32
	Representativeness and Validity	33
	School Participation	33
	Student Participation	34
	Sampling Accuracy of the Estimates	34
	Validity of the Measures of Self-Reported Drug Use	34
	Consistency and the Measurement of Trends	35

DETAILED CONTENTS (continued)

<i>Chapter 4</i>	Prevalence of Drug Use Among Eighth, Tenth, and Twelfth Grade Students	37
	Prevalence and Frequency of Drug Use in 1993: All Students	37
	Lifetime, Annual, and Monthly Prevalence and Frequency	37
	Daily Prevalence	48
	Noncontinuation Rates	52
	Prevalence Comparisons for Important Subgroups	54
	Sex Differences	54
	Differences Related to College Plans	64
	Regional Differences	65
	Differences Related to Population Density	67
	Differences Related to Parental Education	68
	Racial/Ethnic Differences	69
<i>Chapter 5</i>	Trends in Drug Use	75
	Trends in Prevalence 1975-1993: Twelfth Graders	75
	Trends in Prevalence 1991-1993: Eighth and Tenth Graders	99
	Trends in Noncontinuation Rates: Twelfth Graders	104
	Comparison Among Subgroups in Trends in Prevalence: Twelfth Graders Only	106
	Sex Differences in Trends	108
	Trend Differences Related to College Plans	113
	Regional Differences in Trends	115
	Trend Differences Related to Population Density	118
	Differences in Trends by Socioeconomic Status	122
	Racial/Ethnic Differences in Trends	130
<i>Chapter 6</i>	Use at Earlier Grade Levels	135
	Incidence of Use by Grade Level	136
	Trends in Use at Earlier Grade Levels	142
<i>Chapter 7</i>	Degree and Duration of Drug Highs	173
	Degree and Duration of Highs among Twelfth Graders	173
	Trends in Degree and Duration of Drug Highs	175

Chapter 1

INTRODUCTION

This two-volume report presents the results of the nineteenth national survey of drug use and related attitudes among American high school seniors, the fourteenth such survey of American college students, and the third such survey of eighth and tenth grade students. Volume I contains the results from the secondary school samples of eighth, tenth, and twelfth graders. The results from college students and young adults are reported in Volume II.

All of these data derive from the ongoing national research and reporting program entitled *Monitoring the Future: A Continuing Study of the Lifestyles and Values of Youth*, which is conducted at the University of Michigan's Institute for Social Research and has been funded through a series of investigator-initiated research grants from the National Institute on Drug Abuse. In the past the study was sometimes called the National High School Senior Survey, because each year, since 1975, a representative sample of all seniors in public and private high schools in the coterminous United States is surveyed. However, the study also surveys: (a) representative samples of young adults from previous graduating classes who are administered follow-up surveys by mail; (b) representative samples of American college students one to four years past high school, who are included in these follow-up samples; and, (c) since 1991, annual surveys of eighth and tenth grade students.

SURVEYS OF SECONDARY SCHOOL STUDENTS

Two of the major topics included in this series of annual reports are (1) the prevalence of drug use among American secondary school students (specifically in eighth, tenth, and twelfth grades), and (2) trends in use by those students. Distinctions are made among important demographic subgroups in these populations. Data on grade of first use, trends in use at lower grade levels, and intensity of drug use also are reported. Key attitudes and beliefs about drug use, and perceptions of certain relevant aspects of the social environment are included as potential explanatory factors.

The annual surveys of eighth and tenth grade students use procedures and measures that closely parallel those for high school seniors. Two instead of six questionnaire forms are used to survey eighth and tenth grade students, and therefore, fewer variables are measured on the younger students.

SURVEYS OF COLLEGE STUDENTS AND YOUNG ADULTS GENERALLY

Data on the prevalence and trends in drug use among young adults who have completed high school are included in this report series. These data are reported primarily in Volume II, although a brief summary of them is given in Chapter 2 of this volume, "Overview of Key Findings." The period of young adulthood (late teens to late twenties) is particularly important because this tends to be the period of peak use for many drugs.

Monitoring the Future

The Monitoring the Future study design calls for continuing follow-up panel studies—through age 32—of a subsample of the participants in each participating senior class, beginning with the class of 1976. In 1993 representative samples of the graduating classes of 1979 through 1992, corresponding to modal ages of 19 to 32 provided survey data. Comprehensive results from this young adult population are presented in Volume II.

Two chapters in Volume II present data on college students specifically. Trend data are provided since 1980, the first year that a good national sample of college students one to four years past high school was available from the follow-up survey. College students have not usually been well represented in national household surveys, because many college students live on campus in group dwellings (dormitories, fraternities, and sororities), which are often not included in household surveys. (The National Household Survey on Drug Abuse, conducted in earlier years by NIDA, and now by the Substance Abuse and Mental Health Services Administration, was revised in 1991 to include such group dwellings.)

CONTENT AREAS COVERED IN THIS REPORT

Initially, eleven separate classes of drugs were distinguished for this series of reports: marijuana (including hashish), inhalants, hallucinogens, cocaine, heroin, opiates other than heroin (both natural and synthetic), stimulants (more specifically, amphetamines), sedatives, tranquilizers, alcohol, and tobacco. This particular organization of drug use classes was chosen to heighten comparability with a parallel series of publications based on the National Institute on Drug Abuse's National Household Surveys on Drug Abuse. Separate statistics also are presented for several sub-classes of drugs within these more general classes: PCP and LSD (both hallucinogens), barbiturates and methaqualone (both sedatives), the amyl and butyl nitrites (both inhalants), and crack and other cocaine. A number of these drugs came onto the American scene after the study began, and were added to the questionnaires in subsequent years. Trend data for PCP and nitrites are available since 1979 when questions about the use of these drugs were added to the study because of increasing concern over their rising popularity and possibly deleterious effects. For similar reasons, a single question about crack cocaine was added to the 1986 survey and more detailed questions on crack were added in 1987. MDMA or "ecstasy" was added in 1989 (to follow-up surveys only) and crystal methamphetamine ("ice") was added in 1990. Barbiturates and methaqualone, two components of the "sedatives" class as used here, have been separately measured from the outset. Data for them are presented separately because their trend lines are substantially different. Anabolic steroids were added in 1989 because of reports of their increasing illicit use among young people.

Practically all of the information reported here deals with illicit use. Respondents are asked to exclude any occasions on which they used any of the psychotherapeutic drugs under medical supervision. (Some data on the medically supervised use of such drugs are contained in the full 1977, 1978, 1981, and 1983 volumes in this series. A separate article discusses trends in the medical use of these drugs.¹)

¹Johnston, L. D., O'Malley, P. M., & Bachman, J. G. (1987). Psychotherapeutic, licit, and illicit use of drugs among adolescents: An epidemiological perspective. *Journal of Adolescent Health Care*, 8, 36-51.

Throughout this report we have chosen to focus attention on drug use at the higher frequency levels rather than simply report proportions who have ever used various drugs. This is done to help differentiate levels of seriousness, or extent, of drug involvement. While there is no public consensus on what levels or patterns of use constitute "abuse," there is surely a consensus that higher levels of use are more likely to have detrimental effects for the user and society. We have also introduced indirect measures of dosage per occasion, by asking respondents the duration and intensity of the highs they usually experience with each type of drug. Chapter 7 reports those results.

For both licit and illicit drugs, separate chapters are devoted to grade of first use; the students' own attitudes and beliefs; the attitudes, beliefs, and behaviors of others in their social environment; and perceived drug availability. Some of these variables have proven to be important explanators of observed secular trends in use.

Chapter 10, "Other Findings from the Study," discusses use of nonprescription stimulants including diet pills, stay-awake pills, and the "look-alike" pseudo-amphetamines. Questions on these substances were placed in the survey beginning in 1982 because the use of such substances appeared to be on the rise, and some respondents inappropriately included them in their answers about amphetamine use. Their inclusion affected the observed trends.

Chapter 10 also presents trend results from a set of questions about marijuana use at a daily or near-daily level. These questions were added to enable us to develop a more complete individual history of daily use over a period of years. They reveal some interesting facts about the frequent users of this drug.

PURPOSES AND RATIONALE FOR THIS RESEARCH

Perhaps no area has proven more clearly appropriate for the application of systematic research and reporting than the drug field. It is a rapidly changing field. It has importance for the well-being of the nation, and a large amount of legislative and administrative intervention is addressed to it. Young people are often at the leading edge of social change—and this has been particularly true of drug use. The massive upsurge in illicit drug use during the last twenty-five years has proven to be a youth phenomenon; the onset of use is most likely to occur during adolescence. Young adults in their twenties are also among the age groups at highest risk for illicit drug use: indeed, the widespread epidemic of the last twenty years really began on the nation's college campuses. From one year to the next, particular drugs rise or fall in popularity, and related problems occur for youth, for their families, for governmental agencies, and for society as a whole. This year's findings show that changes continue to take place: rather disturbing changes. Further, now that trend data are available on younger adolescents, the trend story has become more complex.

One of the major purposes of the Monitoring the Future series is to develop an accurate picture of the current drug use situation and trends. This is a formidable task, given the illicit and illegal nature of most of the phenomena under study. A reasonably accurate picture of the basic size and contours of the illicit drug use problem among young Americans is a prerequisite for rational public debate and policy making. In the absence of reliable

Monitoring the Future

prevalence data, substantial misconceptions can develop and resources can be misallocated. In the absence of reliable data on *trends*, early detection and localization of emerging problems are more difficult. In addition, assessments of the impact of major historical and policy-induced events are much more conjectural.

The study also monitors a number of factors with which we hoped to be able to *explain* the changes observed in drug use. Many are discussed in this series of volumes. They include peer norms regarding drugs, beliefs about the dangers of drugs, perceived availability, and so on. In fact, monitoring these factors has made it possible to examine a central policy issue for the country in its war on drugs—namely the relative importance of supply reduction effects vs. demand reduction effects in bringing about some of the observed declines in drug use.

In addition to accurately assessing prevalence and trends and trying to determine the causes of them, the Monitoring the Future study also has other important research objectives. Among them: helping to determine which young people are at greatest risk for developing various patterns of drug abuse; gaining a better understanding of the lifestyles and value orientations associated with various patterns of drug use, and monitoring how those orientations are shifting over time; determining the immediate and more general aspects of the social environment associated with drug use and abuse; determining how major transitions in social environment (entry into military service, civilian employment, college, unemployment) or in social roles (marriage, pregnancy, parenthood) affect drug use; determining the life course of the various drug-using behaviors from early adolescence to middle adulthood; distinguishing such "age effects" from cohort and period effects in determining drug use; determining the effects of social legislation on various types of substance use; and, determining the changing connotations of drug use and changing patterns of multiple drug use among youth. We believe that the differentiation of period, age, and cohort effects in substance use of various types has been a particularly important contribution of the project. It is one that its cohort-sequential research design is especially well-suited to make.² Readers interested in publications dealing with any of these other areas should write the authors at the Institute for Social Research, The University of Michigan, Ann Arbor, Michigan, 48106-1248.

²For an elaboration and discussion of the full range of objectives of this research in the domain of substance abuse see Johnston, L.D., O'Malley, P.M., Bachman, J.G., and Schuelenberg, J. (1993). *The aims, objectives, and rationale of the Monitoring the Future Project*. (Monitoring the Future Occasional Paper 34). Ann Arbor, MI: Institute for Social Research.

Chapter 2

OVERVIEW OF KEY FINDINGS

This monograph reports findings through 1993 from the ongoing research and reporting series entitled *Monitoring the Future: A Continuing Study of the Lifestyles and Values of Youth*. The study has consisted of in-school surveys of nationally representative samples of high school seniors each year since 1975 and of eighth and tenth grade students each year since 1991. In addition, follow-up surveys, conducted by mail, have been carried out on representative subsamples of the respondents from each previously participating twelfth grade (beginning in 1976). (Beginning in 1993, follow-up surveys have been conducted of subsamples of eighth and tenth grade classes initially surveyed two years earlier. Results from these surveys are not included in this report.)

Findings on the prevalence and trends in drug use and related factors are presented in this report for secondary school students and also for young adult high school graduates 19-32 years old. Trend data are presented for varying time intervals, covering the past nineteen years in the case of the high school senior population. For college students, a particularly important subset of the young adult population on which there currently exist no other nationally representative data, we present detailed prevalence and trend results covering a fourteen year interval (since 1980) in Volume II of this report. The high school dropout segment of the population—about 15%-20% of an age group—is of necessity omitted from the coverage of these populations, though this omission should have a negligible effect on the coverage of college students³. An appendix to this report discusses the likely impact of omitting dropouts from the sample coverage at senior year. Very few students will have left school by eighth grade, of course, and relatively few by the end of tenth grade, so the results of the school surveys at those levels should be generalizable to the great majority of the relevant age cohorts.

A number of important findings emerge from these five national populations—eighth grade students, tenth grade students, twelfth grade students, college students, and all young adults through age 32 who are high school graduates. They have been summarized and integrated in this chapter so that the reader may quickly get an overview of the key results. However the detailed findings on college students and all young adults are presented separately in Volume II of this report, which is published a few months subsequent to Volume I. Because so many populations, drugs, and prevalence intervals are discussed here, a single integrative table is included in this chapter (Table 1) showing the 1991-1993 two-year trends for all drugs on all five populations.

³Data from the follow-up panels of participants in eighth and tenth grade should soon permit us to correct this omission by providing prospective data on the drug-using behaviors of dropouts.

Footnotes for Table 1

^aUse of "any illicit drugs" includes any use of: marijuana, hallucinogens, cocaine (powder or crack), or heroin; or any use of opiates other than heroin, stimulants, barbiturates, or tranquilizers not under a doctor's orders.

^b"Use of any illicit drugs other than marijuana" includes any use of: hallucinogens, cocaine (powder or crack), or heroin; or any use of opiates other than heroin, stimulants, barbiturates, or tranquilizers not under a doctor's orders.

^cFor 12th graders, college students and young adults, "Use of any illicit drugs, including inhalants" includes any use of: marijuana, inhalants, hallucinogens, cocaine (powder or crack), or heroin; or any use of opiates other than heroin, stimulants, barbiturates, or tranquilizers not under a doctor's orders. For 8th and 10th graders, the use of other opiates and barbiturates has been excluded, because these younger respondents appear to overreport use (perhaps because they include the use of nonprescription drugs in their answers).

^d12th grade, college students, and young adults only: Data based on five questionnaire forms in 1991-1993; N for 12th graders is five-sixths of N indicated. N for college students is 1250 in 1993, and N for young adults is 5480.

^eInhalants are unadjusted for underreporting of amyl and butyl nitrites; hallucinogens are unadjusted for underreporting of PCP.

^f12th grade and young adults only: Data based on a single questionnaire form; N for 12th graders is one-sixth of N indicated in 1991-1993. N for young adults is 1250 in 1993.

^g12th grade, college students, and young adults only: This drug was asked about in two of the six questionnaire forms. N is one-third of N indicated for 12th graders. In 1993, N for college students is 500, and N for young adults is 2500.

^h12th grade, college students, and young adults only: Data based on four questionnaire forms in 1990-1993; N is four-sixths of N indicated for 12th graders. In 1993, N for college students is 1000, and N for young adults is 4230.

ⁱ8th, 10th, 12th grades: In 1993, data based on one of two questionnaire forms for the 8th and 10th grades and on three of six questionnaire forms for the 12th grade. N is one-half of N indicated for these three groups. College students and young adults: In 1993, data were based on three questionnaire forms. N for college students in 1993 is 750. N for young adults is 3700.

^jData based on one questionnaire form. For 12th graders, N is one-sixth of N indicated. For 8th and 10th graders, N is one-half of N indicated.

^kYoung adults only: Data based on one questionnaire form. N in 1993 is 1250.

Approximate N's:

8th Grade	= 17,500 in 1991; 18,600 in 1992; 18,300 in 1993
10th Grade	= 14,800 in 1991; 14,800 in 1992; 15,300 in 1993
12th Grade	= 15,000 in 1991; 15,800 in 1992; 16,300 in 1993
College Students	= 1410 in 1991; 1490 in 1992; 1490 in 1993
Young Adults	= 6600 in 1991; 6800 in 1992; 6700 in 1993

TRENDS IN ILLICIT DRUG USE

- In the previous volume in this series we noted that there was an increase in the use of a number of illicit drugs among the eighth graders and some reversals among the seniors in key attitudes and beliefs. More specifically, the proportions seeing great risk in using drugs began to decline as did the proportions saying they disapproved of use. We stated that these developments were "very important because they could presage an end to the improvements in the drug situation that the nation may be taking for granted" (page 7). Unfortunately, that is exactly what it presaged: The use of illicit drugs rose sharply in 1993 in all three grade levels as negative attitudes and beliefs about them eroded further. So, 1993 was a year in which a turnaround in the long decline occurred for a number of drugs among the nation's secondary school students.
- **Marijuana** use rose sharply in all three grade levels. In the case of eighth graders, this was the second year of increase. Among college students and all young adults, however, marijuana use leveled, following an earlier rise in use. One in forty high school seniors is a daily marijuana user (2.4%, up from 1.9% in 1992, see Table 1). This is still far below the peak rate of 10.7% daily use reached in 1978.
- Among seniors, the proportions using **any illicit drug other than marijuana** in the past year rose from 14.9% to 17.1%, a rate which is still substantially below the 34% peak rate in 1981. There was little change for college students or young adults, 13% of whom report such use.
- In the last couple of years we noted an increase in the use of **LSD**—a drug of the late 1960s and early 1970s—among college students and young adults. In 1992, all five populations showed an increase in annual prevalence of LSD use though the one-year increase was statistically significant only among eighth graders (from 1.7% to 2.1%). In 1993, the eighth, tenth, and twelfth graders showed an increase, and this time only the twelfth grade change was significant. The 1989-1992 increase for college students (from 3.4% to 5.7%), and for young adults (from 2.7% to 4.3%) ended in 1993.

Just prior to the significant increase in use among seniors, there was a significant 4.3% decline in 1992 and a nonsignificant, but continued decline in 1993 in the proportion seeing great risk associated with trying LSD. In 1992 there was also a two percentage point decline (nonsignificant) in the proportion disapproving it and this trend continued in 1993. Since LSD was one of the earliest drugs popularly used in the overall American drug epidemic, there is a distinct possibility that young people—particularly the youngest cohorts, like the eighth graders—are not as concerned about the risks of use. They

Monitoring the Future

have had less opportunity to learn vicariously about the consequences of use by observing others around them, or to learn from intense media coverage of the issue. This type of "generational forgetting" could set the stage for a whole new epidemic of use.

- Prescription-controlled *stimulants*—one of the most widely used classes of drugs taken illicitly (i.e., outside of medical regimen)—also showed evidence of a turnaround in 1993, with annual and 30-day prevalence rates increasing among four of the five populations. (Young adults were the exception.) Annual prevalence had fallen from 20% in 1982 to 7% in 1992 among seniors and from 21% to 4% among college students. This increase in use among seniors in 1993 followed a sharp drop in perceived risk a year earlier. In 1993, perceived risk continued to decline and disapproval of amphetamine use began to decline as well. This pattern is consistent with our theoretical position that perceived risk can drive both use and disapproval.
- The *inhalants* constitute another class of abusable substance where we observe a troublesome increase in 1993. This class of drugs is defined by the form of the substance and its mode of administration—fumes or gases which are inhaled to get high. It includes common household substances such as glues, aerosols, butane, solvents, and so on. One class of inhalants, *amyl and butyl nitrites*, became somewhat popular in the late 1970s, but their use has almost been eliminated. For example, annual prevalence among twelfth grade students was 6.5% in 1979 but 0.9% in 1993.

When the nitrites are removed from consideration it appears that all other inhalants taken together have had an upward trend in use, from 3.0% among seniors in 1976 to 7.0% in 1993. It appears from the retrospective usage data supplied by twelfth grade students that the increase in inhalant use (unadjusted to include the nitrites) also increased at lower grade levels, where inhalant use is more common, during the late 1980s. In 1993 all five populations showed some modest increase in inhalant use, though only the increases in eighth and tenth grade (both of which increased last year as well) reached statistical significance. Some 11% of the 1993 eighth graders and 8% of the tenth graders indicated use in the prior 12 months, making inhalants the most widely used class of illicitly used drugs for eighth graders and the third most widely used (after marijuana and stimulants) for the tenth graders. The inhalants can and do cause death, and tragically, this often occurs among youngsters in their early teens.

- The overall prevalence of **crack** cocaine levelled in 1987 at relatively low prevalence rates, at least within these populations. (This occurred despite the fact that the crack phenomenon continued a process of diffusion to new communities that year.) Then it declined until 1993, when annual prevalence held steady at 1.5% for seniors (down from 3.9% in 1987). Among young adults one to ten years past high school, annual prevalence was 1.3%, but only 0.6% among college students—both relatively unchanged since 1991. In high school, annual crack prevalence among the college-bound is lower than among those not bound for college (1.2% vs. 2.7%). There is now rather little regional variation in crack use.

We believe that the particularly intense media coverage of the hazards of crack cocaine, which took place quite early in what could have been a considerably more serious epidemic, likely had the effect of "capping" that epidemic early by deterring many would-be users and by motivating many experimenters to desist use. While 2.6% of seniors report ever having tried crack, only 0.7% report use in the past month, indicating noncontinuation by 74% of those who try it. The longer-term downward trend can be explained both in terms of lower initiation rates among students and higher noncontinuation rates.

Unfortunately, while use did not rise in 1993, perceived risk and disapproval dropped in all three grade levels, which could presage an increase in use in 1994.

- **Cocaine** in general began to decline a year earlier than crack; between 1986 and 1987 the annual prevalence rate dropped dramatically by roughly four-tenths in all three populations studied.⁴ As we had predicted earlier, the decline occurred when young people began to see experimental and occasional use—the type of use they are most likely to engage in—as more dangerous; and this happened by 1987, probably partly because the hazards of cocaine use received extensive media coverage in the preceding year, but almost surely in part because of the cocaine-related deaths in 1986 of sports stars Len Bias and Don Rogers.

In 1992, this broad decline continued, with annual prevalence falling by nonstatistically significant amounts in all populations *except* eighth graders, who actually showed a statistically significant increase in use. Annual prevalence of cocaine use fell by about two-thirds among the three populations for which long-term data are available. In 1993 cocaine use remained stable in all five populations except the young adults, where use continued to decline. Again, the story regarding attitudes and beliefs is more troubling.

⁴Unless otherwise specified, all references to "cocaine" refer to the use of cocaine in any form, including crack.

Monitoring the Future

Having risen substantially since 1986, the perceived risk of using cocaine in general showed no further change in 1991 among seniors and actually showed some (nonsignificant) decline in 1992. In 1993, perceived risk for cocaine other than crack fell sharply in all grades and disapproval began to decline in all grades, though not as sharply as perceived risk. As with crack, these changes in attitudes and beliefs do not auger well for usage rates next year.

Through 1989, there was no decline in perceived availability of cocaine; in fact, it rose steadily after 1984 suggesting that availability played no role in bringing about the substantial downturn in use. After 1989, however, perceived availability has fallen some among seniors; the decline may be explained by the greatly reduced proportions of seniors who say they have any friends who use, because friendship circles are an important part of the supply system. Eighth and tenth graders reported a significant increase in the availability of crack and other cocaine in 1992, but there was no significant change in 1993.

As with all the illicit drugs, lifetime cocaine prevalence climbs with age, exceeding 30% by age 28. Unlike all of the other illicit drugs, active use—i.e., annual prevalence or monthly prevalence—also climbs after high school.

- **PCP** use fell sharply, from an annual prevalence of 7.0% in 1979 to 2.2% in 1982 among high school seniors. It reached a low point of 1.2% in 1988, increased a bit to 2.4% in 1989, and then fell back to 1.4% by 1991, where it has remained through 1993. For the young adults, the annual prevalence rate is now only 0.2%.
- The annual prevalence of **heroin** use has been very steady since 1979 among seniors at 0.4% to 0.6%. (It had fallen from 1.0% in 1975.) It stands at 0.5% in 1993. The heroin statistics for young adults and college students have also remained quite stable in recent years at low rates (about 0.1% to 0.2%). Eighth and tenth graders have an annual prevalence about the same as, or slightly higher than twelfth graders (0.7%) which is probably due to the fact that the eventual dropouts are captured in the lower grades but not in twelfth grade. Their rates remained unchanged in 1993.
- The use of **opiates other than heroin** had been fairly level over most of the life of the study. Seniors had an annual prevalence rate of 3% to 6% since 1975. In 1991, however, the first recent significant decline (from 4.5% to 3.5%) was observed, though no further changes occurred in 1992 or 1993. Young adults in their twenties have generally shown a very gradual decline from 3.1% in 1986 to 2.2% in 1993; college students have likewise shown a slow decrease, from 3.8% in 1982-1984 to 2.5% in 1993. Data are not reported for younger grade levels

because we believe the students are not accurately discriminating among the drugs which should be included or excluded from this class.

- A long and substantial decline, which began in 1977, occurred for *tranquilizer* use among high school seniors. By 1992 annual prevalence reached 2.8% compared to 11% in 1977, but there was a significant increase in 1993 to 3.5%. For the young adult sample, annual prevalence has now declined to 3.1% and for the college student sample to 2.4%.
- The long-term gradual decline in *barbiturate* use, which began at least as early as 1975, when the study began, halted in 1988; the annual prevalence among seniors fell to 3.2%, compared to 10.7% in 1975. (It stands at 3.4% in 1993.) Annual prevalence of this class of sedative drugs is even lower among the young adult sample (1.9%), and lower still among college students specifically (1.5%). For these groups there has been little further change since 1988. As with the opiates other than heroin, we do not include data here for lower grades because we believe the younger students have more problems with the proper classification of relevant drugs.
- *Methaqualone*, another sedative drug, has shown quite a different trend pattern than barbiturates. Its use rose steadily among seniors from 1975 to 1981, when annual prevalence reached 8%. It then fell rather sharply to 0.5% by 1991 and stands at 0.2% in 1993. Use also fell among all young adults and among college students, which had annual prevalence rates of only 0.3% and 0.2%, respectively in 1989—the last year in which they were asked about this drug. In recent years, shrinking availability may well have played a role in this drop, as legal manufacture and distribution of the drug ceased. Because of its very low usage rates, only the seniors are now asked about their use of this drug.
- In sum, five classes of illicitly used drugs which have had an impact on appreciable proportions of young Americans in their late teens and twenties are *marijuana*, *cocaine*, *stimulants*, *LSD*, and *inhalants*. In 1993, high school seniors showed annual prevalence rates of 26%, 3%, 8%, 7%, and 7%, respectively. Among college students in 1993, the comparable annual prevalence rates are 28%, 3%, 4%, 5%, and 4%; and for all high school graduates one to ten years past high school (young adults) the rates are 25%, 5%, 4%, 4%, and 2%. It is worth noting that LSD has climbed in the rankings because it either has not declined, or in some cases has increased, during a period in which cocaine, amphetamines, and other drugs have declined appreciably. The *inhalants* have become relatively more important for similar reasons.

Monitoring the Future

Clearly, cocaine is relatively more important in the older age group and *inhalants* are relatively more important in the younger ones. In fact, *inhalants* are the most widely used of the illicit drugs in eighth grade.

Indeed, a new index of illicit drug use has been introduced in Table 1 this year, which includes *inhalants* in the definition of illicit drugs, because of their importance among the younger adolescents. Certainly the use of *inhalants* reflects a form of illicit, psychoactive drug use. The inclusion makes relatively little difference in the illicit drug-index prevalence rates for the older age groups, but considerable difference for the younger ones.

- The annual prevalence among seniors of over-the-counter *stay-awake pills*, which usually contain caffeine as their active ingredient, nearly doubled between 1982 and 1990, increasing from 12% to 23%. Since 1990 this statistic has fallen back some to 19% in 1993. Increases also occurred among the college-age young adult population (ages 19-22), where annual prevalence had been as high as 26% in 1989, but is now down to 19% in 1993.

The other two classes of nonprescription stimulants—the *look-alikes* and the over-the-counter *diet pills*—have also shown some fall-off among both seniors and young adults in recent years. Still, among seniors some 23% of the females have tried diet pills by the end of senior year, 12% have used them in the past year, and 5% in just the past month.

College-Noncollege Differences in Illicit Drug Use

- American college students (defined here as those respondents one to four years past high school who were actively enrolled full-time in a two- or four-year college) show annual usage rates for a number of drugs which are about average for their age group, including *any illicit drug*, *marijuana* specifically (although their rate of *daily marijuana use* is about two-thirds what it is for the rest of their age group, i.e., 1.9% vs. 2.7%), *hallucinogens*, *MDMA*, *heroin*, *LSD*, *opiates other than heroin*, and *tranquilizers*. For several categories of drugs, however, college students have rates of use which are below those of their age peers, including *any illicit drug other than marijuana*, *cocaine*, *crack* cocaine specifically, and *barbiturates*. They have a slightly higher rate of use for *inhalants* (3.8% vs. 2.7%).

Since college-bound seniors had below average rates of use on all of these illicit drugs while they were in high school, their eventually attaining parity on many of them reflects some closing of the gap. As results from the study published elsewhere have shown, this college effect of "catching up" is largely explainable in terms of differential rates of leaving the parental home and of getting married. College

students are more likely than their age peers to have left the parental home and its constraining influences, and less likely to have entered marriage with its constraining influences.

- In general, the trends since 1980 in illicit substance use among American college students have been found to parallel those of their age peers not in college. That means that for most drugs there has been a decline in use over the interval. Further, all young adult high school graduates through age 28, as well as college students taken separately, show trends which are highly parallel for the most part to the trends among high school seniors, although declines in the active use of many of the drugs over the past half decade have been proportionately larger in these two older populations than among high school seniors. In 1993, this general parallel in trends was not evident; the upturn seen among the secondary school students was not replicated in the post-high school population.

Male-Female Differences in Illicit Drug Use

- Regarding sex differences in three populations (seniors, college students, and young adults), males are more likely to use ***most illicit drugs***, and the differences tend to be largest at the higher frequency levels. ***Daily marijuana use*** among high school seniors in 1993, for example, is reported by 3.3% of males vs. 1.5% of females; among all young adults by 3.3% of males vs. 1.6% of females; and among college students, specifically, by 2.6% of males vs. 1.3% of females. The only significant exception to the rule that males are more frequently users of illicit drugs than females occurs for ***stimulant*** use in high school, where females are at the same level or slightly higher. The sexes also attain near parity on ***stimulant, tranquilizer, barbiturate, heroin,*** and ***other opiate*** use among the college and young adult populations.
- In the eighth and tenth grade samples, however, there are fewer sex differences in the use of drugs—perhaps because the girls tend to date older boys who are in age groups considerably more likely to use drugs. There is little male-female difference in eighth and tenth grades, for example, in the use of ***inhalants, cocaine, and crack***. As with the older age groups, ***stimulant*** use is slightly higher among females.

TRENDS IN ALCOHOL USE

- Regarding ***alcohol*** use in these age groups, several findings are noteworthy. First, despite the fact that it is illegal for virtually all high school students and most college students to purchase alcoholic beverages, experience with alcohol is almost universal among them (67% of eighth graders have tried it, 81% of tenth graders, 87% of twelfth graders, and 91% of college students) and active use is

Monitoring the Future

widespread. Most important, perhaps, is the widespread occurrence of occasions of heavy drinking—measured by the percent reporting five or more drinks in a row at least once in the prior two-week period. Among eighth graders this statistic stands at 14%, among tenth graders at 23%, among twelfth graders at 28%, and among college students at 40%. After the early twenties this behavior recedes somewhat, reflected by the 34% found in the entire young adult sample.

- Regarding trends in alcohol use, during the period of recent decline in the use of marijuana and other illicit drugs there appears not to have been any "displacement effect" in terms of any increase in alcohol use among seniors. (It was not uncommon to hear such a displacement hypothesis asserted.) If anything, the opposite seems to be true. Since 1980, the monthly prevalence of alcohol use among seniors has gradually declined, from 72% in 1980 to 51% in 1993. **Daily use** declined from a peak of 6.9% in 1979 to 2.5% in 1993; and the prevalence of drinking **five or more drinks in a row** (binge drinking) during the prior two-week interval fell from 41% in 1983 to 28% in 1993—nearly a one-third decline.

In 1993 there were no statistically significant changes in any of the populations in the prevalence of drinking in the prior 30-days, i.e., "current prevalence." There was a significant increase in the binge drinking rate for the tenth grade population. Eighth graders showed increases on both measures, though they were not statistically significant.

College-Noncollege Differences in Alcohol Use

- The data from college students show a quite different pattern in relation to alcohol use. They show less drop-off in monthly prevalence since 1980 (82% to 72% in 1993) and slightly less decline in **daily use** (6.5% in 1980 to 3.2% in 1993). There has also been little change in **occasions of heavy drinking**, which is at 40% in 1993—considerably higher than the 28% among high school seniors. Since both their noncollege-age peers and high school students have been showing a net decrease in occasions of heavy drinking since 1980, the college students stand out as having maintained a very high rate of binge or party drinking. Since the college-bound seniors in high school are consistently less likely to report occasions of heavy drinking than the noncollege-bound, this reflects their "catching up and passing" their peers after high school.
- In most surveys from 1980 onward, college students have had a **daily drinking** rate (3.2% in 1993) which is slightly lower than that of their age peers (4.3% in 1993), suggesting that they are more likely to confine their drinking to weekends, on which occasions they tend to drink a lot. Again, college men have much higher rates of daily drinking than

college women: 5.9% vs. 1.1%. The rate of daily drinking has fallen considerably among the noncollege group, from 8.7% in 1981 to 4.3% in 1993.

Male-Female Differences in Alcohol Use

- There remains a quite substantial sex difference among high school seniors in the prevalence of *occasions of heavy drinking* (21% for females vs. 35% for males in 1993); this difference generally has been diminishing very gradually since the study began over a decade ago.
- There also remain very substantial sex differences in alcohol use among college students, and young adults generally, with males drinking more. For example, 49% of college males report having five or more drinks in a row over the previous two weeks vs. 33% of college females. However, there has been little change in the gender differences between 1980 and 1993.

TRENDS IN CIGARETTE SMOKING

- A number of important findings have emerged from the study concerning *cigarette smoking* among American adolescents and young adults. Of greatest importance is the fact that by late adolescence sizeable proportions of young people still are establishing regular cigarette habits, despite the demonstrated health risks associated with smoking. In fact, since the study began in 1975, cigarettes have consistently comprised the class of substance most frequently used on a daily basis by high school students.
- While the *daily smoking* rate for seniors did drop considerably between 1977 and 1981 (from 29% to 20%), it has remained basically level since then (19% in 1993), despite the appreciable downturn which has occurred in most other forms of drug use (including alcohol) during this period. And, despite all the adverse publicity and restrictive legislation addressed to the subject during the 1980's, the proportion of seniors who perceive "great risk" to the user of suffering physical (or other) harm from pack-a-day smoking has risen only 6.5% since 1980 (to 70% in 1993). That means that nearly a third of seniors still do not feel there is a great risk associated with smoking.
- The story may be even more troublesome at the lower grade levels. While we do not have long-term trends from eighth and tenth graders, their current smoking rates were up significantly from 1992 to 17% and 25%, respectively. Of particular concern, only 53% of the eighth grade students and 61% of the tenth grade students think that a pack-a-day smoker runs a great risk of harm from that behavior. This fact suggests that the health message has not reached American youngsters

Monitoring the Future

at the ages when most of the eventual smokers first initiate smoking. Further, there is no indication of any increase in perceived risk (or of disapproval) of smoking in these age groups. Given that cigarette smoking is the greatest preventable cause of death and disease in the country, the need for a more intense and effective prevention effort aimed at younger children is clearly very great.

Age and Cohort-Related Differences in Cigarette Smoking

- Initiation of daily smoking most often occurs in grades 6 through 9 (i.e., at modal ages 11-12 to 14-15), with rather little further initiation after high school, although a number of light smokers make the transition to heavy smoking in the first two years after high school. Analyses presented in this volume and elsewhere have shown that cigarette smoking shows a clear "cohort effect." That is, if a class (or birth) cohort establishes an unusually high rate of smoking at an early age relative to other cohorts, it is likely to remain high throughout the life cycle.
- As we reported in the "Other Findings from the Study" chapter in the 1986 volume in this series, some 53% of the half-pack-a-day (or more) smokers in senior year said that they had tried to quit smoking and found they could not. Of those who were daily smokers in high school, nearly three-quarters were daily smokers 7 to 9 years later (based on the 1985 survey), despite the fact that in high school only 5% of them thought they would "definitely" be smoking 5 years hence. Clearly, the smoking habit is established at an early age; it is difficult to break for those young people who have it; and young people greatly overrate their own ability to quit. And with the addition of eighth and tenth grade students to the study, we now know that younger children are even more likely than older ones to underestimate the dangers of smoking.

College-Noncollege Differences in Cigarette Smoking

- A striking difference exists between college-bound and noncollege-bound high school seniors in terms of smoking rates. For example, smoking half-pack or more a day is more than twice as prevalent among the noncollege-bound (19% vs. 8%). Among respondents one to four years past high school, those not in college show the same dramatically higher rate of smoking compared to that found among those who are in college, with half-pack-a-day smoking standing at 20% and 9%, respectively.

Male-Female Differences in Cigarette Smoking

- Since 1980, among college students, females have had slightly higher probabilities of being daily smokers. This long-standing sex difference has not been true of their age peers who are not in college.

- In the late seventies, among high school seniors, females caught up to, and passed, males in their rates of **daily smoking**. Both sexes then showed a decline in use followed by a long, fairly level period. In the early nineties males have reached the same rate of daily smoking as females.

RACIAL/ETHNIC COMPARISONS

While we have published articles elsewhere on ethnic differences in drug use, this is only the third volume in this series to include prevalence and trend data for the three largest ethnic groupings—whites, blacks, and Hispanics taken as a group. (Sample size limitations simply do not allow finer subgroup breakdowns unless many years are combined.) Further, 1991 was the first year in which we had data on eighth and tenth graders, for whom ethnic comparisons would be less likely to be affected by differential dropout rates among the three groups, than would be true for seniors. A number of interesting findings emerge in these comparisons, and the reader is referred to Chapters 4 and 5 for a full discussion of them.

- Black seniors have consistently shown lower usage rates on most drugs, licit and illicit, than white students; and we now know that this also is true at the lower grade levels. In some cases, the differences are quite large.
- Black students have a much lower prevalence of **daily cigarette smoking** than white students (4% vs. 21% in senior year) because their smoking rate continued to decline after 1983, while the rate for whites stabilized.
- In twelfth grade, **binge drinking** is much less likely to be reported by black students (13%) than by white (31%) or Hispanic students (27%).
- In twelfth grade, of the three groups, whites have the highest rates of use on a number of drugs, including **inhalants, hallucinogens, LSD** specifically, **barbiturates, amphetamines, tranquilizers, opiates other than heroin, alcohol** and **cigarettes**. In 1993 **marijuana** usage rates are about equivalent for whites and Hispanics, but whites have previously had the highest rates.
- However, in senior year, Hispanics have the highest usage rate for a number of the most dangerous drugs: **cocaine, crack, other cocaine, and heroin**. Further, in eighth grade, Hispanics have the highest rates not only on these drugs, but on many of the others, as well. For example, in eighth grade, the lifetime prevalence for Hispanics, whites, and blacks is 20%, 11%, and 9% for **marijuana**; 7%, 4%, and 1% for **hallucinogens**; 52%, 47%, and 34% for **cigarettes**; 21%, 13%, and 11% for **binge drinking**; etc. In other words, Hispanics have the highest rates of use for nearly all drugs in eighth grade, but not in twelfth, which suggests that their considerably higher dropout rate (compared

Monitoring the Future

to whites and blacks) may change their relative ranking by twelfth grade. Hispanics on average also may have a tendency to begin use earlier—a hypothesis yet to be tested.

- With regard to trends, seniors in all three racial/ethnic groups exhibited the recent decline in **cocaine** use, although black seniors did not show as large an increase in use as did whites and Hispanics; therefore, their decline was less steep.
- For virtually **all of the illicit drugs**, the three groups have tended to trend in parallel. Because white seniors had achieved the highest level of use on a number of drugs—including **stimulants, barbiturates, methaqualone, and tranquilizers**—they also had the largest declines; blacks have had the lowest rates, and therefore, the smallest declines.
- Important racial/ethnic differences in **cigarette smoking** have emerged among seniors during the life of the study. In the late 70's, the three groups were fairly similar in their smoking rates; all three mirrored the general decline in smoking from 1977-1981. Since 1981, however, a considerable divergence has emerged: Smoking rates have declined very little, if at all, for whites and Hispanics, but the rates for blacks continued to decline steadily. As a result, in 1993 the daily smoking rates for blacks is one-fifth that for whites.

DRUG USE IN EIGHTH GRADE

It may be useful to focus specifically on the youngest age group in the study—the eighth graders—who are about 13 to 14 years old, because the exceptional level of use that they already have attained helps illustrate the urgent need this country has to continue to address the problems of substance abuse among its young.

- By eighth grade 67% of youngsters report having tried **alcohol** and more than a quarter (26%) say they have already been drunk at least once.
- **Cigarettes** have been tried by nearly half of eighth graders (45%) and 17%, or one in seven, say they have smoked in the prior month. Only 52% say they think there is great risk associated with being a pack-a-day smoker.
- **Smokeless tobacco** has been tried by 30% of the male eighth graders, is used currently by 11% of them, and is used daily by 2.9%. Rates are far lower among the female eighth graders.
- Among eighth graders, almost one in five (19%) have used **inhalants** and 5% say they have used in the past month. This is the only class of

drugs for which use is substantially higher in eighth grade than in tenth or twelfth grade.

- **Marijuana** has been tried by one in every eight eighth graders (13%), and has been used in the prior month by 5.1%.
- A surprisingly large number say they have tried prescription-type **stimulants** (12%); 3.6% say they have used them in the prior 30 days.
- Relatively few eighth graders say they have tried most of the other **illicit drugs** yet. (This is consistent with the retrospective reports from seniors, which have been included in this series in previous years.)

But the proportions having at least some experience with them still is not inconsequential: **tranquilizers** (4.4%), **LSD** (3.5%), **other hallucinogens** (1.7%), **crack** (1.7%), **other cocaine** (2.4%), **heroin** (1.4%), and **steroids** (1.6% overall, and 2.5% among males.)

- The very large numbers who have already begun use of the so-called "gateway drugs" (tobacco, alcohol, inhalants, and marijuana) suggests that a substantial number of eighth grade students are already at risk of proceeding further to such drugs as LSD, cocaine, amphetamines, and heroin.

SUMMARY AND CONCLUSIONS

To summarize the findings on trends, over the last decade or so there have been appreciable declines in the use of a number of the **illicit drugs** among seniors, and even larger declines in their use among American college students and young adults. However, as we have previously warned, the stall in these favorable trends in all three populations in 1985, as well as an increase in active **cocaine** use that year, should serve as a reminder that these improvements are not inevitable and cannot be taken for granted. (Further, during the eighties, the use of **inhalants** other than nitrites continued to rise.)

While the general decline resumed in 1986 and, most importantly, was joined by the start of a decline in **cocaine** use in 1987 and **crack** use in 1988, in 1992 we heard a number of alarm bells sounding. While the seniors continued to show improvement on a number of measures in 1992, the college students and young adults did not. Further, the attitudes and beliefs of seniors regarding drug use began to soften. Perhaps of greatest importance, the eighth graders exhibited a significant increase in **marijuana, cocaine, LSD, and hallucinogens other than LSD**, as well as a not-quite significant increase in **inhalant** use. (In fact, all five populations showed some increase on **LSD**, continuing a longer term trend for college students and young adults.)

In 1993 still more alarms went off. The eighth graders continued to show an increase in their use of a number of drugs and (as their prior shifts in attitudes and beliefs foretold) the tenth graders and twelfth graders joined them. Rises are seen in a number of the so-called

Monitoring the Future

"gateway drugs"—in this case *marijuana*, *cigarettes*, and *inhalants*—which may bode ill for the use of later drugs in the usual sequence of involvement. The softening of attitudes about *crack* and other forms of *cocaine* also is a basis for concern.

As this study has demonstrated over the years, changes in perceived risk and disapproval have been important causes of the downturns which have occurred in the use of a number of drugs. These beliefs and attitudes surely are in turn influenced by the amount and nature of the public attention being paid to the drug issue. The fact that this attention has declined so substantially in the past few years may help to explain why the increases in perceived risk and disapproval among students ceased, and some clear backsliding has begun.

Of particular concern here is not only the possibility that there may be an increase in the use of particular drugs like LSD and inhalants, but that we may be seeing the beginning of a turnaround in the drug abuse situation more generally among our youngest cohorts—perhaps because they have not had the same opportunities for vicarious learning from the adverse drug experiences of people around them and people they learn about through the media. Clearly there is a danger that, as the drug epidemic has subsided considerably, newer cohorts have far less opportunity to learn through informal means about the dangers of drugs. This may mean that the nation must redouble its efforts to be sure that they learn these lessons through more formal means—from schools, parents, and focused messages in the media, for example—and that this more formalized prevention effort become institutionalized so that it will endure for the long term.

The following facts help to put into perspective the magnitude and variety of substance use problems which remain among American young people:

- By the end of eighth grade, one-third (32%) of American secondary school students have tried an *illicit drug* (if inhalants are included as an illicit drug). Almost two-fifths of tenth graders have done so (39%), and nearly one-half of twelfth graders (47%).
- By their late twenties, over 75% of America's young adults today have tried an *illicit drug*, including over 50% who have tried some *illicit drug other than marijuana*. These figures do not include inhalants.
- By age 28, about one-third of young Americans have tried *cocaine*; and as early as the senior year of high school 6% have done so. Roughly one in every forty seniors (2.6%) have tried the particularly dangerous form of cocaine called *crack*: in the young adult sample one in twenty-five (4.3%) have tried it.
- One in forty (2.4%) of high school seniors in 1993 smoke *marijuana daily*, as is true among young adults aged 19 to 28 (2.4%). Among seniors in 1993, 9.6% had been daily marijuana smokers at some time for at least a month, and among young adults the comparable figure is 12.8%.

Chapter 2 Overview of Key Findings

- Some 28% of seniors have had *five or more drinks in a row* at least once in the prior two weeks, and such behavior tends to increase among young adults one to four years past high school. The prevalence of such behavior among male college students reaches 49%.
- Some 30% of seniors are current *cigarette* smokers and 19% already are current daily smokers, and these numbers are *rising*. In addition, many of the lighter smokers will convert to heavy smoking after high school.
- Thus, despite the improvements in recent years, it is still true that this nation's secondary school students and young adults show a level of involvement with illicit drugs which is greater than has been documented in any other industrialized nation in the world. Even by longer-term historical standards in this country, these rates remain extremely high. Heavy drinking also remains widespread and troublesome; and certainly the continuing initiation of a large and growing proportion of young people to cigarette smoking is a matter of the greatest public health concern.
- Finally, we note the seemingly unending capacity of pharmacological experts and amateurs to discover new substances with abuse potential that can be used to alter mood and consciousness, as well the potential for our young people to "discover" the abuse potential of existing products, like Robitussin™, and to "rediscover" older drugs, such as LSD. While as a society we have made significant progress on a number of fronts in the fight against drug abuse, we must continually be preparing for, and remaining vigilant against, the opening of new fronts, as well as the re-emergence of trouble on older ones.
- The drug problem is not an enemy which can be vanquished, as in a war. It is more a recurring and relapsing problem which must be contained to the extent possible on a long term, ongoing basis.

Chapter 3

STUDY DESIGN AND PROCEDURES

This chapter presents the research design, sampling plans, and field procedures used in both the in-school surveys of the eighth, tenth, and twelfth grade students, and the follow-up surveys of young adults. Related methodological issues such as response rates, population coverage, and the validity of the measures will also be discussed. We begin with a description of the design which has been used consistently over 19 years to survey high school seniors; then the much more recently instituted design for eighth and tenth graders is described. Finally, the designs for the *follow-up* surveys of former twelfth graders, and former eighth and tenth graders, are covered.⁵

RESEARCH DESIGN AND PROCEDURES FOR THE SURVEYS OF SENIORS

The data from high school seniors are collected during the spring of each year; data collection began with the class of 1975. Each year's data collection takes place in approximately 125 to 140 public and private high schools selected to provide an accurate representative cross-section of high school seniors throughout the coterminous United States (see Figure 1).

The population under study. There are several reasons for choosing the senior year of high school as an optimal point for monitoring the drug use and related attitudes of youth. First, the completion of high school represents the end of an important developmental stage in this society, since it demarcates both the end of universal public education and, for many, the end of living in the parental home. Therefore, it is a logical point at which to take stock of the cumulated influences of these two environments on American youth. Further, the completion of high school represents the jumping-off point from which young people diverge into widely differing social environments and experiences so senior year represents a good time at which to take a "before" measure upon which to calculate changes which may be attributable to the many environmental and role transitions which occur in young adulthood. Finally, there are some important practical advantages to building a system of data collections around samples of high school seniors. The need for systematically repeated, large-scale samples from which to make reliable estimates of change requires that considerable stress be laid on cost efficiency as well as feasibility. The last year of high school constitutes the final point at which a reasonably good national sample of an age-specific cohort can be drawn and studied economically.

The omission of dropouts. One limitation in the design to date has been that it did not include in the target population those young men and women who drop out of high school before graduation—between 15 and 20 percent of each age cohort nationally, according to U.S. Census statistics. The omission of high school dropouts does introduce biases in the

⁵For a more detailed description of the study design, see Bachman, J.G., Johnston, L.D., & O'Malley, P.M. (1991). *Monitoring the Future project after seventeen years: Design and procedures*. (Monitoring the Future Occasional Paper 33.) Ann Arbor, MI: Institute for Social Research.

FIGURE 1

Counties Included in One Year's Data Collection

NOTE: Counties may contain multiple schools and up to three grade levels each.

estimation of certain characteristics of the entire age group; however, for most purposes, the small proportion of dropouts sets outer limits on the bias. Further, since the bias from missing dropouts should remain just about constant from year to year, their omission should introduce little or no bias in *change* estimates. Indeed, we believe the changes observed over time for those who finish high school are likely to parallel the changes for dropouts in most instances. An Appendix to this volume addresses the likely effects of the exclusion of dropouts on estimates of prevalence of drug use and trends in drug use among the entire age cohort; the reader is referred to it for a more detailed discussion of this issue.

In the future, as the eighth and tenth grade follow-up surveys actually gather data from prospectively defined panels of dropouts, we hope to be able to make direct estimates of the extent to which their omission from the senior samples causes an underestimate for the age group as a whole. In 1993, the first such two-year follow-up occurred, but since the data files are completed considerably later than those based on the in-school surveys, the findings were not available for inclusion here.

Sampling procedures. A multi-stage random sampling procedure is used for securing the nationwide sample of high school seniors each year. Stage 1 is the selection of particular geographic areas, Stage 2 the selection (with probability proportionate to size) of one or more high schools in each area, and Stage 3 the selection of seniors within each high school. This three-stage sampling procedure has yielded the numbers of participating schools and students over the years shown in Table 2.

Questionnaire administration. About ten days before the administration, the seniors are given flyers explaining the study. The actual questionnaire administrations are conducted by the local Institute for Social Research representatives and their assistants, following standardized procedures detailed in a project instruction manual. The questionnaires are administered in classrooms during a normal class period whenever possible; however, circumstances in some schools require the use of larger group administrations.

Questionnaire format. Because many questions are needed to cover all of the topic areas in the study, much of the questionnaire content intended for seniors is divided into six different questionnaire forms which are distributed to participants in an ordered sequence that ensures six virtually identical subsamples. (Five questionnaire forms were used between 1975 and 1988.) About one-third of each questionnaire form consists of key or "core" variables which are common to all forms. All demographic variables, and nearly all of the drug use variables included in this report, are contained in this core set of measures. Many of the questions dealing with attitudes, beliefs, and perceptions of relevant features of the social environment are in a single form only, and are thus based on one-sixth as many cases (approximately 2,600) in 1989-1993 or one-fifth as many cases in 1975-1988 (approximately 3,300). All tables in this report give the sample sizes upon which the statistics are based, stated in terms of weighted numbers of cases (which are roughly equivalent to the actual numbers of cases).

RESEARCH DESIGN AND PROCEDURES FOR THE SURVEYS OF LOWER GRADES

Beginning in 1991 the study was expanded to include nationally representative samples of eighth and tenth grade students. Our intention was to conduct similar surveys on an annual basis and to conduct follow-up surveys of representative sub-samples from each year's sample. The first such follow-ups were implemented in 1993.

In general, the procedures used for the annual surveys of eighth and tenth grade students closely parallel those used for high school seniors, including the procedures for selecting schools and students, questionnaire administrations, and questionnaire formats. A major exception is that only two different questionnaire forms are used, rather than the six used with seniors. Identical forms are used for both eighth and tenth grades, and, for the most part, questionnaire content is drawn from the twelfth grade questionnaires. Thus, key demographic variables and measures of drug use and related attitudes and beliefs are generally identical for all three grades. The two forms used in both eighth and tenth grades have a common core (Parts B and C) that parallels the core used in twelfth grade, and each form has somewhat different questions in Parts A and D. Many fewer questions about lifestyles and values are included in these forms than in the twelfth grade forms, in part because we think that many of these attitudes are more likely to be formed by twelfth grade, and therefore are best monitored there. For the national survey of eighth graders, approximately 160 schools are sampled, and approximately 18,000 to 19,000 students are surveyed. For the tenth graders, approximately 125 schools are sampled, and approximately 15,000 students are surveyed.

The research design calls for follow-up surveys of subsamples of the eighth and tenth graders participating in the study, carried out at two-year intervals, similar to the senior follow-up samples. To date, this plan has influenced the design of the cross-sectional studies of eighth and tenth graders in two important ways. First, in order to "capture" many of the eighth grade participants two years later in the normal tenth grade cross-sectional study for that year, we selected the eighth grade schools by first drawing a sample of high schools and then selecting a sample of their feeder schools which contain eighth graders. This extra stage in the sampling process meant that many of the eighth grade participants in, say, the 1991 cross-sectional survey were also participants in the 1993 cross-sectional survey of tenth graders. Thus, a fair amount of panel data have been generated with no additional cost. However, having followed this design in 1993, we concluded that the saving in follow-up costs did not justify the complexities in sampling, administration, and interpretation. Therefore, we will return to a more simplified design beginning in 1995 in which eighth grade schools will be drawn independently of the tenth grade school sample, and *all* follow-ups of eighth graders will be completed by mail.

RESEARCH DESIGN AND PROCEDURES FOR THE FOLLOW-UP SURVEYS OF SENIORS

Beginning with the graduating class of 1976, each senior class has been followed up annually after high school on a continuing basis, for seven follow-up data collections, which

Monitoring the Future

corresponds to their reaching a modal age of 32.⁶ From the roughly 15,000 to 17,000 seniors originally participating in a given class, a representative sample of 2,400 individuals is chosen for follow-up. In order to ensure sufficient numbers of drug users in the follow-up surveys, those fitting certain criteria of current drug use (that is, those reporting 20 or more uses of marijuana, or any use of any of the other illicit drugs, in the previous 30 days) are selected with higher probability (by a factor of 3.0) than the remaining seniors. Differential weighting then has been used in all follow-up analyses to compensate for the differential sampling probabilities. Because those in the drug-using stratum receive a weight of only .33 in the calculation of all statistics to compensate for their overrepresentation, the actual numbers of follow-up cases are somewhat larger than the weighted numbers reported in the tables. Weights are assigned to compensate for differential probabilities of selection at each stage. Final weights are normalized to average 1.0 (so that the weighted number of cases equals the unweighted number of cases).

The 2,400 selected respondents from each class are randomly assigned to one of two matching groups of 1,200 each; one group is surveyed on even-numbered calendar years, while the other group is surveyed on odd-numbered years. This two-year cycle is intended to reduce respondent burden, and thus yield a better retention rate across the years.

Follow-up procedures. Using information provided by respondents at the time of the senior survey (name, address, phone number, and the name and address of someone who would always know how to reach them), mail contacts are maintained with those selected for inclusion in the follow-up panels. Newsletters are sent each year, and name and address corrections are requested. The questionnaires are sent by certified mail in the spring of each year. A check for \$5.00, made payable to the respondent, is attached to the front of each questionnaire.⁷ Reminder letters and postcards go out at fixed intervals thereafter; finally, those not responding receive a prompting phone call from the Survey Research Center's phone interviewing facility in Ann Arbor. If requested, a second copy of the questionnaire is sent; but no questionnaire content is administered by phone.

Panel retention rates. To date the panel retention rates have remained quite high. In the first follow-up after high school, about 80% of the original panel have returned questionnaires. The retention rate reduces with time, as would be expected. The 1993 panel retention from the class of 1979—the oldest of the panels, now aged 32 (14 years past their first data collection in high school) is 65%.

Corrections for panel attrition. Since, to a modest degree, attrition is associated with drug use, we have introduced corrections into the prevalence estimates presented here for the follow-up panels. These raise the prevalence estimates from what they would be uncorrected, but only slightly. We believe the resulting estimates to be the most accurate obtainable for the population of high school senior graduates but still low for the age group

⁶Further follow-ups will occur at half-decade intervals, beginning with age 35.

⁷Note that, beginning with the Class of 1992, the follow-up checks have been raised to \$10.00 to compensate for the effects of inflation over the life of the study. An experiment conducted on recent classes suggested that the increased payment was justified based on the increased panel retention it achieved.

as a whole, due to the omission of dropouts and absentees from the population covered by the original panels.⁸

REPRESENTATIVENESS AND VALIDITY

School participation. Schools are invited to participate in the study for a two-year period. With very few exceptions, each school from the original sample participating in the first year has agreed to participate for the second. Each year thus far, from 58% to 80% of the high schools invited to participate initially have agreed to do so; for each school refusal, a similar school (in terms of size, geographic area, urbanicity, etc.) is recruited as a replacement.⁹ The selection of replacement schools almost entirely removes problems of bias in region, urbanicity, and the like, that might result from certain schools refusing to participate. Other potential biases could be more subtle, however. If, for example, it turned out that most schools with "drug problems" refused to participate, that would seriously bias the sample. And if any other single factor were dominant in most refusals, that also might suggest a source of serious bias. In fact, however, the reasons for a school refusing to participate are varied and are often a function of happenstance events specific to that particular year; only a very small proportion specifically object to the drug content of the survey. Thus we feel quite confident that school refusals have not seriously biased the surveys.

Schools are selected in such a way that half of each year's sample in each grade level is comprised of schools which participated the previous year, and half is comprised of schools which will participate the next year. This staggered half-sample design is used to check on possible errors in the year-to-year trend estimates due to school turnover. For example, separate sets of one-year trend estimates are computed for seniors using first that half-sample of schools which participated in both 1990 *and* 1991, then the half-sample which participated in both 1991 *and* 1992, and so on. Thus, each one-year trend estimate derived in this way is based on a constant set of at least 65 schools. When the resulting trend data

⁸The intent of the weighting process is to correct for the effects of differential attrition on follow-up drug use estimates. Different weights are used for different substances. Cigarettes, alcohol, and marijuana each have one weight for every follow-up of each graduating class. The weights are based on the observed differences in the distribution on an index of use of the relevant substance based on the follow-up sample compared to the distribution based on the full base-year sample. For example, the distribution on the index of marijuana use in the 1988 follow-up of approximately 1,000 respondents from the class of 1976 was compared to the original 1976 base-year distribution for the entire participating base-year class of 17,000 respondents; and weights were derived which, when applied to the base-year data for only those participating in the 1988 follow-up, would reproduce the original base-year frequency distribution. A similar procedure is used to determine a weight for all illicit drugs other than marijuana combined. In this case, however, an average weight is derived across graduating classes. Thus, the same weight is applied, for example, to all respondents in the follow-up of 1988, regardless of when they graduated from high school.

⁹Response rates for the junior high and middle schools which produce the eighth grade samples are a little more complicated to calculate. Calculation of the response rates for Monitoring the Future eighth grade schools for 1991 and 1992 is complicated by the fact that they are sampled by "network" (or cluster), based on the high school into which they feed. We first draw a representative sample of tenth grade schools, then sample eighth grade schools from the set of feeder schools to each high school. If there are more than two eighth grade schools feeding into a selected high school, we sample two schools. If either of those schools declines, we replace that school with another school in the same network of feeder schools. If no school in the network agrees to participate, then we count that as a refusal; if only one school in a network agrees to participate, but fails to meet a minimum size criterion of approximately one-third of combined enrollment of the chosen schools, that is also counted as a refusal. If only one of the schools agrees to participate, and that one represents at least one-third the combined enrollment of the chosen schools, then we accept that school, and reweight appropriately. Many networks, of course, have only one feeder eighth grade school in the network, in which case, a school refusal is equivalent to a network refusal. Response rates for the 1991 and 1992 eighth grade by network were: 74% and 69%, respectively.

Monitoring the Future

(examined separately for each class of drugs) are compared with trends based on the total samples of schools, the results are highly similar, indicating that the trend estimates are little affected by turnover or shifting refusal rates in the school samples. The absolute prevalence estimates for a given year are not as accurate using just the half-sample, however.

Student participation. In 1993, completed questionnaires were obtained from 90% of all sampled students in eighth grade, 86% in tenth grade, and 84% in twelfth grade. (See Table 1 for response rates in earlier years). The single most important reason that students are missed is absence from class at the time of data collection; in most cases, it is not workable to schedule a special follow-up data collection for absent students. Students with fairly high rates of absenteeism also report above-average rates of drug use; therefore, there is some degree of bias introduced into the prevalence estimates by missing the absentees. Much of that bias could be corrected through the use of special weighting based on the reported absentee rates of the students who did respond; however, we decided not to use such a weighting procedure because the bias in overall drug use estimates was determined to be quite small, and because the necessary weighting procedures would have introduced greater sampling variance in the estimates. Appendix A of one of our earlier reports¹⁰ provides a discussion of this point and the Appendix to the present report shows trend and prevalence estimates which would result if corrections for absentees had been included.

Of course, some students are not absent from class, but simply refuse when asked to complete a questionnaire. However, the proportion of explicit refusals amounts to less than 1% of the target sample.

Sampling accuracy of the estimates. For purposes of this introduction, it is sufficient to note that drug use estimates based on the total sample of seniors each year have confidence intervals that average about $\pm 1\%$. (As shown in Table 3 in Chapter 4, confidence intervals on lifetime prevalence for seniors vary from $\pm 2.5\%$ to smaller than $\pm 0.3\%$, depending on the drug. Confidence intervals for past twelve months, past 30-days, and daily use would be smaller). This means that, had we been able to invite all schools and all seniors in the 48 coterminous states to participate, the results from such a massive survey should be within about one percentage point of our present findings for most drugs at least 95 times out of 100. We consider this to be a high level of sampling accuracy, and one that permits the detection of fairly small changes from one year to the next. Table 2 also presents the confidence intervals for tenth grade and eighth grade students on lifetime prevalence statistics, which are roughly the same as those observed for twelfth graders. Tenth grade confidence intervals vary from $\pm 2.5\%$ to $\pm 0.3\%$, and for eighth grade, confidence intervals vary from $\pm 1.9\%$ to $\pm 0.3\%$.

VALIDITY OF THE MEASURES OF SELF-REPORTED DRUG USE

The question always arises whether sensitive behaviors like drug use are honestly reported. Like most studies dealing with sensitive behaviors, we have no direct, totally objective validation of the present measures; however, the considerable amount of inferential evidence

¹⁰Johnston, L.D., O'Malley, P.M., & Bachman, J.G. (1984). *Drugs and American high school students: 1975-1983*. DHHS (ADM) 85-1374. Washington, D.C.: U.S. Government Printing Office.

that exists strongly suggests that the self-report questions produce largely valid data. A more complete discussion of the contributing evidence which leads to this conclusion may be found in other publications; here we will only briefly summarize the evidence.¹¹

First, using a three-wave panel design, we established that the various measures of self-reported drug use have a high degree of reliability—a necessary condition for validity.¹² In essence, this means that respondents were highly consistent in their self-reported behaviors over a three- to four-year time interval. Second, we found a high degree of consistency among logically related measures of use within the same questionnaire administration. Third, the proportion of seniors reporting some illicit drug use by senior year has reached two-thirds of all respondents in peak years and nearly as high as 80% in some follow-up years, which constitutes *prima facie* evidence that the degree of underreporting must be very limited. Fourth, the seniors' reports of use by their unnamed friends—about which they would presumably have less reason to distort—has been highly consistent with self-reported use in the aggregate in terms of both prevalence and trends in prevalence, as will be discussed later in this report. Fifth, we have found self-reported drug use to relate in consistent and expected ways to a number of other attitudes, behaviors, beliefs, and social situations—in other words, there is strong evidence of "construct validity." Sixth, the missing data rates for the self-reported use questions are only very slightly higher than for the preceding nonsensitive questions, in spite of the instruction to respondents to leave blank those drug use questions they felt they could not answer honestly. And seventh, the great majority of respondents, when asked, say they would answer such questions honestly if they were users.

This is not to argue that self-reported measures of drug use are valid in all cases. In the present study we have gone to great lengths to create a situation and set of procedures in which students feel that their confidentiality will be protected. We have also tried to present a convincing case as to why such research is needed. We think the evidence suggests that a high level of validity has been obtained. Nevertheless, insofar as there exists any remaining reporting bias, we believe it to be in the direction of underreporting. Thus, we believe our estimates to be lower than their true values, even for the obtained samples, but not substantially so.

Consistency and the measurement of trends. One further point is worth noting in a discussion of the validity of the findings. The Monitoring the Future project is designed to be sensitive to changes from one time period to another. Accordingly, the measures and procedures have been standardized and applied consistently across each data collection. To the extent that any biases remain because of limits in school and/or student participation, and to the extent that there are distortions (lack of validity) in the responses of some

Monitoring the Future

students, it seems very likely that such problems will exist in much the same way from one year to the next. In other words, biases in the survey estimates will tend to be consistent from one year to another, which means that our measurement of *trends* should be affected very little by any such biases. The smooth and consistent nature of most trend curves reported for the various drugs provides rather compelling empirical support for this assertion.

Chapter 4

PREVALENCE OF DRUG USE AMONG EIGHTH, TENTH, AND TWELFTH GRADE STUDENTS

This section summarizes the levels of drug use reported by the national samples of eighth, tenth, and twelfth grade students surveyed in 1993. Prevalence and frequency of use data are included for lifetime use, use in the past year, and use in the past month. The prevalence of current daily use also is provided. In addition, comparisons are given for key subgroups in the population based on sex, college plans, region of the country, population density (or urbanicity), socioeconomic status, and racial/ethnic identification.

It should be noted that all of the prevalence statistics given in this section are based on students in attendance on the day of the survey administration. Selected prevalence rate estimates for seniors, reflecting adjustments for absentees, as well as for dropouts, may be found in Appendix 1 to this report. (Twelfth graders had 16% absent from the 1993 administration.) The adjustments for absenteeism and dropping out would be much smaller for eighth and tenth grades, since they have lower rates of absenteeism (10% and 14%, respectively) and much lower rates of dropping out.

PREVALENCE AND FREQUENCY OF DRUG USE IN 1993: ALL STUDENTS

Lifetime, Annual, and Monthly Prevalence and Frequency

Table 4 provides prevalence rates for the use of all drugs at all three grade levels in lifetime, past twelve months, past 30 days, and daily in past 30 days. Frequency of use for each drug within each prevalence period is provided in Table 5a; Figure 2 presents the drugs ranked by lifetime prevalence within each grade level. Table 3 provides the 95% confidence interval around the lifetime prevalence estimate for each drug.

- Less than half of all seniors (43%) report *illicit drug use* at some time in their lives. (See Table 1, Chapter 2).
- More than a third (38%) of those seniors reporting any illicit drug use have used *only marijuana* (16% of the sample). A quarter of all seniors (27%) report having used an *illicit drug other than marijuana* at some time.^{13,14}

¹³Use of "other illicit drugs" includes any use of hallucinogens, cocaine, or heroin *or* any use of other opiates, stimulants, barbiturates, methaqualone (excluded since 1990), or tranquilizers that are not under a doctor's orders.

¹⁴Indexes of any illicit drug use, or any illicit drug use other than marijuana, have not been calculated for eighth and tenth graders because usable data do not exist for certain component classes of drugs—in particular, sedatives and opiates other than heroin. Questions on these drugs were included in the questionnaires given to eighth and tenth graders, but the results lead us to believe that some respondents were including nonprescription drugs in their answers, resulting in exaggerated prevalence rates. Therefore the data are omitted for these two classes of drugs, and for the usage indexes that they would influence.

NOTE: '—' indicates data not available. '*' indicates less than .05 percent.

SOURCE: The Monitoring the Future Study, the University of Michigan.

*Unadjusted for known underreporting of certain drugs. See text for details.

^bBased on the data from the revised question, which attempts to exclude the inappropriate reporting of non-prescription stimulants.

- **Marijuana** is by far the most widely used illicit drug among seniors and tenth graders, and among eighth graders it follows inhalants in terms of lifetime use. Thirty-five percent of seniors reported some **marijuana** use in their lifetime, 26% reported some use in the past year, and 16% reported some use in the past month. Among tenth graders, 24% reported some marijuana use in their lifetime, 19% reported some use in the past year, and 11% reported some use in the past month. Among eighth grade students, marijuana has a 13% lifetime prevalence, although inhalants have a higher lifetime prevalence (19%).
- In tenth and twelfth grades, **inhalants** have lifetime prevalence rates of 18% and 17%, respectively, which makes them the second most prevalent of the illicit drugs other than marijuana. These are followed closely by **stimulants**, with lifetime prevalence rates for both tenth and twelfth grade at 15%. However, in terms of current use, inhalants rank lower at these grade levels since more of the early users have discontinued use.
- **Hallucinogens** are the next most widely used class of substances among seniors (11% lifetime prevalence) primarily due to the prevalence of LSD use (10%). The same is true for eighth and tenth graders.
- About one in seventy seniors (1.4%) have tried the specific classes of inhalants known as **amyl and butyl nitrites**. These inhalants have been sold legally in the past and go by the street names "poppers" or "snappers" and such brand names as Locker Room and Rush. Use of nitrites was not asked of eighth and tenth grade students.

Because we included questions specifically about nitrite use for the first time in one 1979 senior questionnaire form, we discovered that some users of amyl and butyl nitrites did not report themselves to be inhalant users, as they should have. We were able to make estimates of the degree to which inhalant use was being underreported. As a result, all inhalant prevalence estimates made since then have been corrected for nitrite use. This correction has made very little difference in recent years because of the low rates of nitrite use.

We also discovered in 1979, when specific questions about **PCP** use were added, that some users of PCP did not report themselves as users of hallucinogens, even though PCP is explicitly included as an example in the questions about hallucinogens. Thus, from 1979 onward, the **hallucinogen** prevalence and trend estimates for seniors also have been adjusted upward to correct for this known underreporting. PCP use is not asked of eighth

Monitoring the Future

and tenth graders.¹⁵ Once again, this correction has made rather little difference in recent years among seniors, because the rate of PCP use is so low.

- Lifetime prevalence among seniors for the specific hallucinogenic drug **PCP** now stands at 2.9%, substantially lower than the lifetime prevalence of the other most widely used hallucinogen, **LSD** (10.3%).
- The use of **cocaine** now ranks lower than it used to, with lifetime prevalence among seniors at 6.1%, and the lifetime prevalence for eighth and tenth graders at 2.9% and 3.6%, respectively.
- **Crack cocaine** has a low prevalence in all grade levels; a lifetime prevalence of 1.7% for grade 8, 1.8% for grade 10, and 2.6% for grade 12. Crack is a form of cocaine which comes in small chunks or "rocks," and which can be smoked to produce a more rapid and intense high. It came onto the American scene very rapidly during the mid-1980s.
- Of all seniors, 2.6% indicated having tried **crack** at some time in their lives. Roughly half of that number (1.5%) reported use in the past year, but only one-fourth that number (0.7% of all seniors) reported use in the last month. Among those seniors who used **cocaine** in any form during the past year (3.3%), about 45% used it in crack form, usually in addition to using it in powdered form.
- **Heroin** is the least commonly used of the illicit drugs with about 1% of each grade level reporting any experience. Use is 1.4% for eighth grade students, 1.3% for tenth grade students, and 1.1% for twelfth grade students. This unusual pattern (younger students having a higher prevalence level), which appears in a number of studies, may reflect the fact that heroin users are considerably more likely to have left school by senior year.
- **Tranquilizers** fall in the middle of the rankings, with lifetime prevalence rates of 4.4%, 5.7%, and 6.4% for grades 8, 10, and 12.
- **Sedatives and opiates other than heroin** are also in the middle ranking; both have been used by 6.4% of seniors. (Data for eighth and tenth graders are not reported, as is explained in an earlier footnote.)

¹⁵Because the data to adjust inhalant and hallucinogen use for seniors are available from only a single questionnaire form in a given year, the original uncorrected variables will be used in most relational analyses. We believe relational analyses will be least affected by these underestimates and that the most serious impact is on prevalence estimates, which have been adjusted appropriately. Today, the very low levels of use for nitrites and PCP—the two drugs which were used to adjust the estimates for inhalants and hallucinogens, respectively—are so low that these adjustments are hardly relevant any longer. Therefore, questions about their use have not been included in the eighth and tenth grade questionnaires.

- Within the general class sedatives, the specific drug *methaqualone* is used by considerably fewer seniors (0.8% lifetime prevalence) than the much broader subclass of sedatives, *barbiturates* (6.3% lifetime prevalence). Because methaqualone use has become so limited, questions about its use have not been included in the eighth and tenth grade questionnaires.
- The illicit drug classes remain in roughly the same order whether ranked by lifetime, annual, or monthly prevalence, as the data in Figure 2 illustrate. The only important change in ranking occurs for *inhalant use* among the tenth and twelfth graders, for whom inhalants rank lower in terms of current use than was true for lifetime use, because use of some inhalants, like glues and aerosols, tends to be discontinued at a relatively early age.
- Use of either of the two major licit drugs, alcohol and cigarettes, remains more widespread than use of any of the illicit drugs. Seven of every eight students (87%) have tried *alcohol* by twelfth grade; more than half of all seniors (51%) have used it in just the month prior to the survey (Table 4). Even among eighth graders, the number of students who report some alcohol use in their life is high: two-thirds (67%) say they have tried alcohol and a quarter (26%) are current drinkers. However, note in Table 5a that 20% of the eighth graders report using alcohol only once or twice—perhaps having just a few sips. In future years, eighth and tenth graders will be asked to omit occasions involving only a few sips.
- Of perhaps greater concern than the use of alcohol is its use to the point of inebriation: 26% of the eighth graders, 48% of the tenth graders, and 63% of the twelfth graders say they have "*been drunk*" at least once. The prevalence of self-reported drunkenness in the past 30 days is 8%, 20%, and 29%, respectively.
- Another measure of heavy drinking asks respondents on how many occasions within the previous two weeks they had consumed *five or more drinks in a row*. Prevalence rates for this behavior are 14%, 23%, and 28% for the three grades, respectively.
- Nearly two-thirds (62%) of seniors report having tried *cigarettes* at some time, and more than a quarter (30%) smoked at least some in the past month. Even among eighth graders, 45% report having tried cigarettes and 17% used in the past month.
- *Smokeless tobacco* is used by a surprisingly large number of young people. Among eighth, tenth, and twelfth graders, lifetime prevalence rates are 19%, 28%, and 31%, respectively, while current prevalence rates are 7%, 10%, and 11%. As will be discussed further below, the

Monitoring the Future

rates are considerably higher among boys, who account for most of this use.

Anabolic steroids, a class of controlled substances, were added to the study in recent years. These drugs bear some resemblance to other drugs in the study in that they are controlled but find their way into an illicit market. They also carry a particular danger for HIV transmission since they are often taken by injection. They differ from all the other drugs discussed here, however, in that they are not usually taken for their direct psychoactive effects, though they may have some, but rather for their enhancement of the user's musculature. Clearly their potential unintended consequences, including the transmission of HIV, make their illicit use a public health concern. It is for these reasons that they have been added to the study.

- The prevalence rates for ***anabolic steroids*** are relatively low at present. For eighth, tenth, and twelfth graders, lifetime prevalence is 1.6%, 1.7%, and 2.0%, while current prevalence is 0.5%, 0.5%, and 0.7%. (Rates for males are distinctly higher, as will be discussed below.)

While most of the discussion in this volume will focus on prevalence rates for different time periods (i.e., lifetime, annual, and 30-day), some readers will be interested in more detailed information about the frequency with which various drugs have been used in these same time periods. Tables 5a and 5b present such frequency-of-use information in as much detail as the original question and answer sets contain.

Daily Prevalence

Frequent use of illicit or licit drugs is a great concern for the health and safety of adolescents. Tables 9 and 14 and Figure 3 show the prevalence of current daily or near-daily use of the various classes of drugs. For all drugs except cigarettes and smokeless tobacco, respondents are considered daily users if they indicated that they had used the drug on twenty or more occasions in the preceding 30 days. In the case of cigarettes, respondents explicitly state the use of one or more cigarettes per day, and for smokeless tobacco they state using "about once a day" or more often.

- Across all three grade levels, ***cigarettes*** are used daily by more of the respondents than any of the other drug classes: 8%, 14%, and 19% in grades 8, 10, and 12, respectively. In fact, many students say they smoke half-a-pack or more per day (4%, 7%, and 11%).
- Daily use of ***smokeless tobacco*** is considerably lower than cigarette use, at 1.5%, 3.3%, and 3.3%.
- Daily use of ***alcohol*** is next most frequent, at all three grade levels, at 0.8%, 1.6%, and 2.5% in grades 8, 10, and 12.
- ***Marijuana*** still is used on a daily or near-daily basis by about one of every forty seniors (2.4%); many fewer tenth grade students use daily (1.0%), and only 0.4% of eighth grade students report daily use. (See

Various Types of Drugs for Eighth, Tenth, and Twelfth Graders, 1993**

Monitoring the Future

the last chapter of this volume for a discussion of levels of past daily use and cumulative daily use of marijuana.)

- Less than 1% of the senior respondents report daily use of any one of the *illicit drugs other than marijuana*. They report 0.2% daily use of *stimulants*, followed by a number of drug classes at 0.1% or below. While very low, these figures are not inconsequential, because 1% of the high school class of 1993 represents approximately 25,000 individuals.
- As would be expected, the daily use figures for the illicit drugs tend to be lower in eighth and tenth grades. *Marijuana* is used daily by 1.0% of tenth graders, and *inhalants* are used on a daily basis by 0.3% of eighth graders. *Stimulants* are a bit unusual in that tenth grade use is 0.3%, compared with 0.2% among twelfth graders. Otherwise, daily use figures for all other classes of illicit drugs are at or below 0.2%.

NONCONTINUATION RATES

An indication of the proportion of people who try a drug but do not continue to use it can be derived from calculating the percentage, among those who ever used a drug (once or more), who did not use it the 12 months preceding the survey.¹⁶ We use the word "noncontinuation" rather than "discontinuation," since the latter might imply discontinuing an established pattern of use, whereas our current operational definition includes experimental users as well as established users. These noncontinuation rates are provided for all drug classes in Figure 4 for the senior class of 1993. (Only data for seniors are presented here.) It may be seen in Figure 4 that noncontinuation rates vary widely among the different drugs.

- The highest noncontinuation rates observed are for *methaqualone* (75%), *inhalants* (58%), *heroin* (55%), and *PCP* (52%). Many of the inhalants are used primarily at a younger age, and the use of methaqualone may have declined in part, because it is no longer readily available.
- By senior year, a high noncontinuation rate is found for *cocaine* (46%), including *powdered cocaine* (46%). *Crack cocaine* has only a slightly lower noncontinuation rate (42%). All of the *psychotherapeutic drugs* have noncontinuation rates near 45%.
- Because a relatively high proportion of users continue to use *marijuana* at some level over an extended period, it consistently has had one of the lowest noncontinuation rates (26% in 1993) in senior year of any of the illicit drugs.

¹⁶This operationalization of noncontinuation has an inherent problem in that users of a given drug who initiate use during the past year by definition cannot be noncontinuers. Thus, the definition tends to understate the noncontinuation rate, particularly for drugs that tend to be initiated late in high school rather than in earlier years.

FIGURE 4

Noncontinuation Rates: Percent of Twelfth Graders Who Used Drug Once or More in Lifetime but Did Not Use in Past Year, 1993

*Percent of regular smokeless tobacco users (ever) who did not use smokeless tobacco in the last thirty days.

**Percent of regular smokers (ever) who did not smoke at all in the last thirty days.

Monitoring the Future

- Contrary to the widespread belief that **crack** is almost instantly addicting, it is noteworthy that, of the seniors who have ever used crack (2.6%), only about one-fourth (0.7%) are current users and only 0.1% of the total sample are daily users. While there is no question that crack is highly addictive, this evidence suggests that it is not usually addictive on the first use.
- The remaining **illicit drugs** have noncontinuation rates ranging from 31% to 45%.
- In contrast to illicit drugs, noncontinuation rates for the two licit drugs are extremely low. **Alcohol**, which has been tried by nearly all seniors (87%), is used in senior year by nearly all of those who have ever tried it (76% of all seniors) yielding a noncontinuation rate for alcohol of only 13%.
- Noncontinuation is defined differently for **cigarettes**, because cigarette use in the past year is not asked of respondents. The noncontinuation rate is the percentage of those who say they ever smoked "regularly" who report not smoking at all during the past 30 days. Only 17% of seniors who say they were regular smokers have ceased active use.
- Noncontinuation is defined for **smokeless tobacco** much the same way as for cigarettes; it has a low rate of noncontinuation, with only 26% of the lifetime "regular" users not using in the past year.

PREVALENCE COMPARISONS FOR IMPORTANT SUBGROUPS

Sex Differences

In general, higher proportions of males than females are involved in illicit drug use, especially heavy drug use; however, this picture is a somewhat complicated one (see Tables 6 through 9).

- Overall the proportion of twelfth graders using **marijuana** is somewhat higher among males (annual prevalence of 29% vs. 22% among females), but daily use of marijuana is much more frequent among males (3.3% vs. 1.5% for females). This is also true among eighth and tenth grade students. (See Tables 7 and 9.)
- Males also have considerably higher prevalence rates on most other illicit drugs. The annual prevalence rates in senior year tend to be at least one and one-half to two and one-half times as high among males as among females for **nitrites** and the specific drugs **LSD**, **PCP**, **heroin**, **cocaine**, **inhalants**, and **ice**. Compared to females, males report somewhat higher annual rates of use for **marijuana** and **crack**

NOTE: Prevalence of use of each drug was included in all six questionnaire forms with the following exceptions: Inhalants was in five forms; other cocaine was in four forms; alcohol was in three forms; crystal methamphetamine (ice), steroids, and "been drunk" were in two forms; and nitrites, PCP, sedatives, methaqualone and smokeless tobacco were in one form. The N's in Table 7 should be adjusted accordingly (i.e., the approximate N for inhalants is five-sixths of the 12th grade N given in Table 7). See Table 7 for sample sizes.

SOURCE: The Monitoring the Future Study, the University of Michigan.

^a12th grade only: Unadjusted for known underreporting of certain drugs. See text for details.

^bOnly drug use which was not under doctor's orders is included here.

^cParental education is an average score of mother's education and father's education reported on the following scale: (1) Completed grade school or less, (2) Some high school, (3) Completed high school, (4) Some college, (5) Completed college, (6) Graduate or professional school after college. Missing data was allowed on one of the two variables.

^aData based on one questionnaire form. N is one-half of N indicated for the 8th and 10th grades and one-sixth of N indicated for the 12th grade.

^bBased on one of two questionnaire forms for the 8th and 10th grades and on three of six questionnaire forms for the 12th grade. N is one-half of N indicated for all grades.

^cThis measure refers to use of five or more drinks in a row in the past two weeks.

^dParental education is an average score of mother's education and father's education reported on the following scale: (1) Completed grade school or less, (2) Some high school, (3) Completed high school, (4) Some college, (5) Completed college, (6) Graduate or professional school after college. Missing data was allowed on one of the two variables.

cocaine. Further, males account for an even greater share of the frequent or heavy users of these various classes of drugs. For many of these drugs there is little sex difference among eighth and tenth graders. In fact, for some drugs the females have slightly higher rates of use, in eighth grade, including *inhalants*, *stimulants*, and *tranquilizers*. Thus, the sex differences in twelfth grade, with males more likely to use, seem to emerge over the course of middle to late adolescence.

- Even in twelfth grade, females approach the annual prevalence rates for males in the case of *opiates other than heroin*, *tranquilizers*, *barbiturates*, and *stimulants*.
- The number of high school seniors of both sexes who report using *some illicit drug other than marijuana* during the last year are not substantially different (18% for males vs. 16% for females; see Figure 12 in Chapter 5). If one thinks of going beyond marijuana as an important threshold point in the sequence of illicit drug use, then fairly similar proportions of both sexes were willing to cross that threshold at least once during the year. However, on the average, the female "users" take fewer types of drugs and tend to use them with less frequency than their male counterparts.
- The use of *anabolic steroids* is heavily concentrated in the male population, with use among senior males at 2.5% in the past year compared to 0.1% among females. In eighth grade the difference is (1.4% vs. 0.3%).
- Frequent use of *alcohol* tends to be disproportionately concentrated among males. *Daily use*, for example, is reported by 3.6% of the senior males vs. only 1.4% of the senior females. Also, males are more likely than females to drink large quantities of alcohol in a single sitting; 35% of senior males report taking *five or more drinks in a row* in the prior two weeks vs. 21% of senior females.¹⁷ These sex differences are observable at all three grade levels, but they are considerably larger among the older students.
- In recent years, *smoking rates* among seniors have been very similar for males and females. In 1993, slightly more twelfth grade males report *daily smoking* in the past month (19% vs. 18% for females), as well as smoking *half-pack or more per day* (11.6% for males vs. 9.9% for females). Males are more likely to be heavy smokers in the lower

¹⁷Because females tend to weigh less than males, and may metabolize alcohol somewhat differently, the same amount of ingested alcohol would, on average, lead to higher blood alcohol concentrations for females, compared to males. Therefore, the difference in terms of a fixed number of drinks, such as five or more drinks, may not reflect the difference in intoxication rates. The difference in self-reported prevalence of drunkenness among seniors is 11% (35% for males and 24% for females, 30-day), which is slightly less than the 14% difference in having five or more drinks in a row (35% vs. 21%).

Monitoring the Future

grades, as well, but the daily smoking rates are very close for the two sexes.

- **Smokeless tobacco** is used almost exclusively by males. While 20% of the twelfth grade males reported some use in the prior month, only 2% of the females did. Rates of daily use by males are 2.9% among eighth graders, and 6.4% among tenth and twelfth graders. The comparable statistics for females are 0.3%, 0.3%, and 0.4%.

Differences Related to College Plans

Overall, students who say they probably or definitely will complete four years of college (referred to here as the "college-bound") have lower rates of illicit drug use than those who say they probably or definitely will not. (See Tables 6 through 9 and Figure 13 in Chapter 5). It is interesting to note that while the majority of students at all three grade levels expect to complete college, the proportion decreases as grade level increases, even though the lower grades contain 15%-20% who will eventually drop out of high school.

For any given drug, the differences between these two self-identified groups of college- or noncollege-bound students tend to be greatest in the eighth grade. This could reflect an earlier age of onset for the noncollege-bound, and/or the fact that fewer of the eventual dropouts have left school yet, thus increasing the differences in the lower grades.

- Annual **marijuana** use is reported by 24% of the college-bound seniors vs. 29% of the noncollege-bound, but among eighth graders it is reported by only 7% of the college-bound vs. 22% of the noncollege-bound.
- Among 1993 seniors who reported using **any illicit drug other than marijuana** (adjusted), 16% of the college-bound reported any such behavior in the prior year vs. 20% of the noncollege-bound.
- Frequent use of many of these illicit drugs shows even larger contrasts related to college plans (see Table 9). **Daily marijuana** use among seniors, for example, is 1.8 times as high among those who do not plan to attend college (3.6%) as among the college-bound (2.0%). Among eighth and tenth graders it is four to five times as high.
- Frequent alcohol use is also more prevalent among the noncollege-bound. For example, **daily drinking** is reported by 4.4% of the noncollege-bound seniors vs. 1.8% of the college-bound seniors. **Binge drinking** (five or more drinks in a row at least once during the preceding two weeks) is reported by 33% of the noncollege-bound seniors vs. 26% of the college-bound. On the other hand, there are only very small differences between the college-bound and noncollege-bound seniors in lifetime, annual, or monthly prevalence of alcohol use. It is not so much drinking, but rather frequent and heavy drinking, which tends to differentiate these two groups.

- For annual **steroid** use, there is an appreciable difference between the noncollege-bound seniors (2.0% annual prevalence) and the college-bound seniors (0.9%). There is a similar pattern at all three grade levels.
- By far, the largest and most dramatic difference in substance use between the college- and noncollege-bound involves **cigarette** smoking, with 8% of the college-bound seniors smoking **half-a-pack or more daily** compared with 19% of the noncollege-bound seniors. The proportional differences are even larger in the lower grades: 2.2% vs. 11.9% in eighth grade and 4.6% vs. 18.5% in tenth grade. (The absence of dropouts in twelfth grade undoubtedly reduces the ratio, since dropouts have a particularly high rate of smoking.)

Regional Differences

Notable regional differences in rates of illicit drug use among high school seniors may be observed in Tables 6 through 9. See Figure 5 for a **regional division** map of the states included in the four regions of the country as defined by the Census Bureau.

- In 1993, the highest rate of illicit drug use is in the Northeast, where 36% of seniors say they have **used an illicit drug in the past year**, followed by the West (32%) and the North Central (31%). The South continues to have the lowest rate with 28% of the seniors reporting any illicit drug during the year (see Figure 14a in Chapter 5).
- There are very modest, but consistent regional variations in terms of the percentage of seniors using some **illicit drug other than marijuana** (adjusted) in the past year. The Northeast and the West lead for this measure (both at 19%), with the North Central and the South not far behind at 16%.
- Among twelfth graders, there have generally not been large differences in **marijuana** use among the regions, except that the South has typically been lower than the other three. For the younger students, the West is generally somewhat higher than the other three regions. In 1993, annual prevalence among eighth graders in the West is 15%, compared to 6%-9% in the others.
- In the past, regional differences in **cocaine** use have been the largest observed. The West has tended to rank relatively high in the use of an **illicit drug other than marijuana**, due in part to a high level of cocaine use. Currently, the annual prevalence of **cocaine** and **crack** is highest in the West for all three grade levels.
- Other specific illicit substances vary in the extent to which they show regional variation, as Table 7 illustrates for the annual prevalence

FIGURE 5

States Included in the Four Regions of the Country

These are the four major regions of the country as defined by the U.S. Bureau of the Census.

measure. In addition to having the highest levels of *cocaine* and *crack* and *other cocaine* use at all three grade levels, the West also ranks first among the regions in twelfth graders' use of *hallucinogens* and *ice* (not included in Table 7), and in eighth and tenth graders use of *LSD*.

- There consistently has been a large regional difference in the use of *ice*. The highest rate among seniors is in the West at 3.2% annual prevalence, followed by the North Central (1.5%), the South (1.2%), and the Northeast (1.1%).
- The South shows the *lowest* rates of use among seniors for *hallucinogens* (unadjusted), *LSD*, and *opiates other than heroin*; but it also has the highest rate of *tranquilizer* use.
- The North Central stands out for having high rates among seniors of *stimulant* use, *smoking*, and *drinking*. Low rates of use are observed for *tranquilizers* and *cocaine*.
- The annual and 30-day prevalence rates of *alcohol* use among seniors are somewhat lower in the South and West than in the Northeast and North Central regions. The same is true for *binge drinking*, though it is clearly lowest in the West, as is *daily drinking*.
- The North Central and Northeast regions also have higher rates of *daily smoking* in twelfth grade (24% and 21%, respectively) than the South and the West (19% and 13%, respectively). The same pattern is true for the tenth grade students. However, in the eighth grade the regional differences are rather small and inconsistent with those observed in the upper grades.

Differences Related to Population Density

Three levels of population density (or urbanicity) have been distinguished for analytical purposes: (1) large MSA's, which are the 28 largest Metropolitan Statistical Areas in the 1990 Census; (2) other MSA's, which are the remaining Metropolitan Statistical Areas; and (3) non-MSA's, which are the sampling areas not designated as metropolitan by the Census. See Appendix 2 for further detail.

In general, the differences in the use of most illicit drugs across these different sizes of community are small, reflecting how widely illicit drug use has diffused through the population. (See Tables 6 through 9.)

- In twelfth grade, annual *marijuana* use is lower in the nonurban areas (23%) than in the large metropolitan areas (29%), or in the other metropolitan areas (26%).

Monitoring the Future

- On the other hand, **stimulant** use is somewhat higher among tenth and twelfth grade students in nonurban areas than in the metropolitan areas.
- In both eighth and tenth grades **binge drinking** is inversely related to community size. Even in twelfth grade the non-metropolitan areas have the highest rate of alcohol use, though the differences are not large (Table 9).
- With one minor exception, both **cigarette** use and **daily smokeless tobacco** use are highest in the nonurban areas (Table 9) for all three grade levels.

Differences Related to Parental Education

The best measure of family socioeconomic status available in the study is an index of parental education, which is based on the average of the educational levels reported for both parents by the respondent (or on the data for one parent, if data for both are not available). The scale values on the original questions are: (1) completed grade school or less, (2) some high school, (3) completed high school, (4) some college, (5) completed college, and (6) graduate or professional school after college. The average educational level obtained by students' parents has been rising over the years. Tables 6 through 9 give the distributions for 1993.

- By senior year there is rather little association with family socioeconomic status for **most drugs**. This again speaks to the extent to which illicit drug use has permeated all social strata in this society.
- On the other hand, an examination of Table 7 shows that in eighth grade, the lowest socioeconomic stratum does have a somewhat higher rate of use of a number of drugs—particularly **marijuana, having been drunk, cigarettes, and smokeless tobacco**, but to a lesser degree **hallucinogens, LSD, cocaine, crack, stimulants, and tranquilizers**. Few of these relationships are ordinal: rather, the bottom category, or sometimes two categories, stand out as having higher usages rates than the others.

By twelfth grade some of these relationships have actually reversed, with the highest rate of use observed in the upper socioeconomic strata. This is true for **marijuana, hallucinogens, LSD, and alcohol** use (including **binge drinking**), but *not* for **cocaine, crack, or stimulant** use.

The diminished socioeconomic differences by twelfth grade could be explained by the upper- and middle-class youngsters "catching up" with their more precocious peers from poor backgrounds. The difference may also be explained by the impact of dropping out, which is correlated both with social class and drug use. A panel study following eighth

graders, begun in 1993 as a part of this study, should permit us to determine which of these alternative explanations is correct.

- **Daily smoking** comes close to having an inverse ordinal relationship with parental education in eighth and tenth grades.
- The use of **smokeless tobacco** is inversely correlated with parental education at all three grade levels. Thus, tobacco use in general now bears a strong negative relationship to social class among young people.

Racial/Ethnic Differences

Racial/ethnic comparisons for blacks, Hispanics, and whites were added to this monograph series for the first time in 1991.¹⁶ Although the design of this project did not include an oversampling of any minority groups, the large overall sample sizes at each grade level do produce fair numbers of black and Hispanic respondents each year. In the tabular data discussed here, we combine data from two adjacent years to increase the reliability of the estimates. We caution the reader that the sampling error of differences between groups is likely to be larger than would be true for other demographic and background variables such as sex or college plans, because blacks and Hispanics are more likely to be clustered by school. Table 10 gives the lifetime, annual, 30-day, and daily use statistics for the three racial/ethnic groups at all three grade levels, along with the numbers of cases upon which the estimates are based.

- Several general points can be derived from Table 10. First, for virtually **all drugs**, licit and illicit, black **seniors** have reported lifetime and annual prevalence rates which are lower—sometimes dramatically lower—than those for white or Hispanic seniors. This is mostly true for the 30-day and daily prevalence statistics, as well, although there are a few exceptions.
- Second, the same can be said for black students in eighth and tenth grades which means that the low usage rates for blacks in twelfth grade almost certainly are not due to differential dropout rates.
- The third general point is that whites in the twelfth grade have the highest lifetime and annual prevalence rates for many drugs, including: **inhalants, hallucinogens, LSD** specifically, **opiates other than heroin, amphetamines, barbiturates, tranquilizers, and cigarettes**. Not all of these findings replicate at lower grade levels.

¹⁶We recognize that the Hispanic category is a broad one, encompassing people with various Latin American and Caribbean origins, but for the purposes of this monograph the sample sizes unfortunately are too small to differentiate among them. For a more complete treatment of racial/ethnic differences, in which additional subgroups are distinguished and males and females are examined separately within each racial/ethnic category, see Bachman, J.G., Wallace, J.M., Jr., O'Malley, P.M., Johnston, L.D., Kurth, C.L., & Neighbors, H.W. (1991). Racial/ethnic differences in smoking, drinking, and illicit drug use among American high school seniors, 1976-1989. *American Journal of Public Health*, 81, 372-377.

(Table continued on next page)

- Hispanics taken as a group, have the highest lifetime and annual prevalence rates in senior year for some particularly dangerous classes of drugs. These include *cocaine*, *crack*, *other cocaine*, and *heroin*. Their rate of *crack* use is particularly high, compared to the other two racial/ethnic groups. Further, it should be remembered that Hispanics have a considerably higher dropout rate, based on Census Bureau statistics, than whites or blacks, which would tend to diminish any such differences by senior year.
- An examination of the racial/ethnic comparisons at lower grade levels shows Hispanics having higher rates of use not only on all the drugs on which they have the highest prevalence in twelfth grade but on a number of other drugs, as well. For example, in eighth grade 20% of Hispanic students report ever having used *marijuana*, compared to 11% of white students and 9% of black students. For *hallucinogens* the lifetime prevalence in eighth grade for Hispanics, whites, and blacks is 7%, 4%, and 1%; for *tranquilizers*, 7%, 4%, and 3%; for *cigarettes*, 52%, 47%, and 34%. In other words, in eighth grade—before dropout rates begin to accelerate—Hispanics have the highest rate of use of nearly all the drugs; whereas by twelfth grade, whites are highest in most. Certainly the considerably higher dropout rate among Hispanics could explain this shift, and may be the most plausible explanation. Another explanation worth considering is that Hispanics may tend to start using drugs younger, but that whites catch up to, and pass them at older ages. These explanations are not mutually exclusive, of course, and to some degree, both explanations may be true.
- Looking at the daily use figures, we find exceptionally large absolute and proportional differences between the three groups in their rates of *daily cigarette smoking*. Among seniors, whites have a 21% daily smoking rate, Hispanics 12% (which may be low, in part, because of their higher dropout rate), and blacks only 4%. In fact, blacks have much lower smoking rates at all grade levels.
- *Daily drinking* among black seniors is only about two-thirds that for whites and Hispanics, and *daily marijuana* use one-third the rate of the whites.
- Recent *binge drinking* is also lowest among blacks at all grade levels, although the proportional difference is greatest in twelfth grade where 31% of whites report binge drinking and 27% of Hispanics, compared with only 13% of blacks. In eighth grade, Hispanics have the highest rate at 21%, compared with 13% for whites and 11% for blacks.

Chapter 5

TRENDS IN DRUG USE

The beginning of this chapter presents trends in drug use among high school seniors, comparing the nineteen graduating classes of 1975 through 1993. Trends are also presented for grades 8 and 10 based on three years of survey data, 1991 through 1993. As in the previous chapter, the outcomes to be discussed include measures of lifetime use, use during the past year, use during the past month, and daily use. In addition, trends are compared for the key demographic subgroups discussed earlier and trends in noncontinuation rates are also examined.

TRENDS IN PREVALENCE 1975-1993: TWELFTH GRADERS

Tables 11 through 14 give trends in lifetime, annual, 30-day, and current daily prevalence of use for all drugs mentioned in this chapter, based on the past nineteen graduating classes. Figures 6 through 9 provide graphic descriptions of these trends.

- The years 1978 and 1979 marked the crest of a long and dramatic rise in *marijuana* use among American high school students. As Tables 11 through 13 and Figure 9a illustrate, annual and 30-day prevalence of marijuana use leveled between 1978 and 1979, following a steady rise in the preceding years. In 1980, both annual and 30-day prevalence statistics dropped for the first time and continued to decline every year through 1992, except in 1985 when there was a brief pause. Then, in 1993, annual use rose sharply (by 4 percentage points), although at 26% it is still 25 percentage points below its all-time high of 51% in 1979. Thirty-day use also rose significantly from the 1992 level of 11.9% to 15.5% in 1993. Lifetime prevalence began to drop in 1981, though more gradually than annual or 30-day use.¹⁹ Today 35% of all seniors have tried marijuana before leaving high school, up significantly from 1992 when it was 33%, but down from the peak of 60% in 1980. As we will discuss in Chapter 8, there have been substantial changes in the attitudes and beliefs that young people hold in relation to marijuana; and these changes appear to account for much of the long term decline in use, as well as the more recent increase in use.
- Of particular importance were the even sharper fluctuations which have occurred for active *daily marijuana use* (Table 14). Between 1975 and 1978 there was an almost two-fold increase in daily use. The proportion reporting daily use in the class of 1975 (6%) came as a surprise to many; and then that proportion rose rapidly, so that by 1978 one in every nine high school seniors (11%) indicated that he or she

¹⁹Lifetime use declines more gradually than the annual or 30-day statistics because it reflects changes in initiation rates only, whereas annual and 30-day reflect both changes in initiation rates *and* noncontinuation rates.

Footnotes for Table 11-Table 14

- *Use of "any illicit drugs" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, methaqualone (excluded since 1990), or tranquilizers not under a doctor's orders.
- ^bBeginning in 1982 the question about stimulant use (i.e., amphetamines) was revised to get respondents to exclude the inappropriate reporting of non-prescription stimulants. The prevalence rate dropped slightly as a result of this methodological change.
- *Use of "other illicit drugs" includes any use of hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, methaqualone (excluded since 1990), or tranquilizers not under a doctor's orders.
- ^dData based on four questionnaire forms in 1976-1988; N is four-fifths of N indicated. Data based on five questionnaire forms in 1989-1993; N is five-sixths of N indicated.
- *Adjusted for underreporting of amyl and butyl nitrites. See text for details.
- ^fData based on a single questionnaire form; N is one-fifth of N indicated in 1979-1988 and one-sixth of N indicated in 1989-1993.
- ^gQuestion text changed slightly in 1987.
- ^hAdjusted for underreporting of PCP. See text for details.
- ⁱData based on a single questionnaire form in 1986; N is one-fifth of N indicated. Data based on two questionnaire forms in 1987-1989; N is two-fifths of N indicated in 1987-1988 and two-sixths of N indicated in 1989. Data based on six questionnaire forms in 1990-1993.
- ^jData based on a single questionnaire form in 1987-1989; N is one-fifth of N indicated in 1987-1988 and one-sixth of N indicated in 1989. Data based on four questionnaire forms in 1990-1993; N is four-sixths of N indicated.
- *Only drug use which was not under a doctor's orders is included here.
- ^lData based on two questionnaire forms; N is two-sixths of N indicated. Steroid data based on a single questionnaire form in 1989-1990; N is one-sixth of N indicated in 1989-1990.
- ^mData based on five questionnaire forms in 1975-1988, six questionnaire forms in 1989, and one questionnaire form in 1990-1993. N is one-sixth of N indicated in 1990-1993.
- ⁿData based on five questionnaire forms in 1975-1988, six questionnaire forms in 1989-1992, and three of six questionnaire forms in 1993. N is one-sixth of N indicated in 1993.

FIGURE 6

Trends in Lifetime Prevalence of an Illicit Drug Use Index for Twelfth Graders

NOTES: Use of "any illicit drugs" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use which is not under a doctor's orders of other opiates, stimulants, barbiturates, methaqualone (excluded since 1990), or tranquilizers.

Beginning in 1982 the question about stimulant use (i.e., amphetamines) was revised to get respondents to exclude the inappropriate reporting of non-prescription stimulants. The prevalence rate dropped slightly as a result of this methodological change.

Trends in Thirty-Day Prevalence of an Illicit Drug Use Index for Twelfth Graders

NOTES: Use of "any illicit drugs" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use which is not under a doctor's orders of other opiates, stimulants, barbiturates, methaqualone (excluded since 1990), or tranquilizers.

Beginning in 1982 the question about stimulant use (i.e., amphetamines) was revised to get respondents to exclude the inappropriate reporting of non-prescription stimulants. The prevalence rate dropped slightly as a result of this methodological change.

used the drug on a daily or nearly daily basis (defined as use on 20 or more occasions in the last 30 days). In 1979 this rapid and troublesome increase halted, followed by a rapid reversal. By 1992 the daily usage rate had dropped to 1.9%, well below the peak rate of 11% or even the 6% level first observed in 1975. We attribute much of this dramatic decline to a very substantial increase in concerns about possible adverse effects from regular use, and to a growing perception that peers would disapprove of marijuana use, particularly regular use. In 1993, however, for the first time in fifteen years, daily marijuana use increased significantly, from 1.9% in 1992 to 2.4%.

- Until 1978, the proportion of seniors involved in **any illicit drug use** had increased steadily, primarily because of the increase in marijuana use (see Figure 6). About 54% of the classes of 1978 and 1979 reported having taken at least one illicit drug during the prior year, up from our first observation in the class of 1975 of 45%. Between 1979 and 1984, however, the proportion reporting using any illicit drug during the prior year dropped by 1% or 2% annually until 1985, when there was a brief pause in the decline. In 1986 the decline resumed, with annual prevalence dropping significantly to 27% in 1992. As with marijuana, the annual prevalence rate increased sharply in 1993, to 31%.
- As Figure 6 and Table 11 illustrate, between 1976 and 1982 there was a very gradual, steady increase in the proportion of twelfth graders using **some illicit drug other than marijuana**²⁰. The annual prevalence of such behaviors (Figure 7), which rose by nine percentage points between 1976 and 1981 (from 25% to 34%), began a steady decline to 15% in 1992. The 30-day prevalence figure actually began to drop a year earlier—in 1982—and exhibited the largest proportional drop, from 22% in 1981 to 6% in 1992 (see Figure 8 and Table 13). In 1993, these measures showed a significant increase, indicating that the turnaround in 1993 was not confined to marijuana use. Annual prevalence rose from 15% to 17%.

Most of the earlier rise in the use of some **illicit drug other than marijuana** appeared to be due to the increasing popularity of cocaine with this age group between 1976 and 1979, and then to the increasing use of stimulants between 1979 and 1981. As stated earlier, we believe that the upward shift in stimulant use was exaggerated because some respondents included instances of using over-the-counter stimulants in their reports of amphetamine use. Figures 6 through 8 show trends which, beginning in 1982, were revised to exclude the inappropriate reporting of these non-prescription stimulants.

²⁰Included under the definition of "any illicit drug other than marijuana is any use of hallucinogens, cocaine, and heroin, as well as any use which is not under a doctors orders of other opiates, stimulants, barbiturates, tranquilizers, and quaaludes (excluded since 1990). Not included are the following: alcohol, tobacco, inhalants, and steroids.

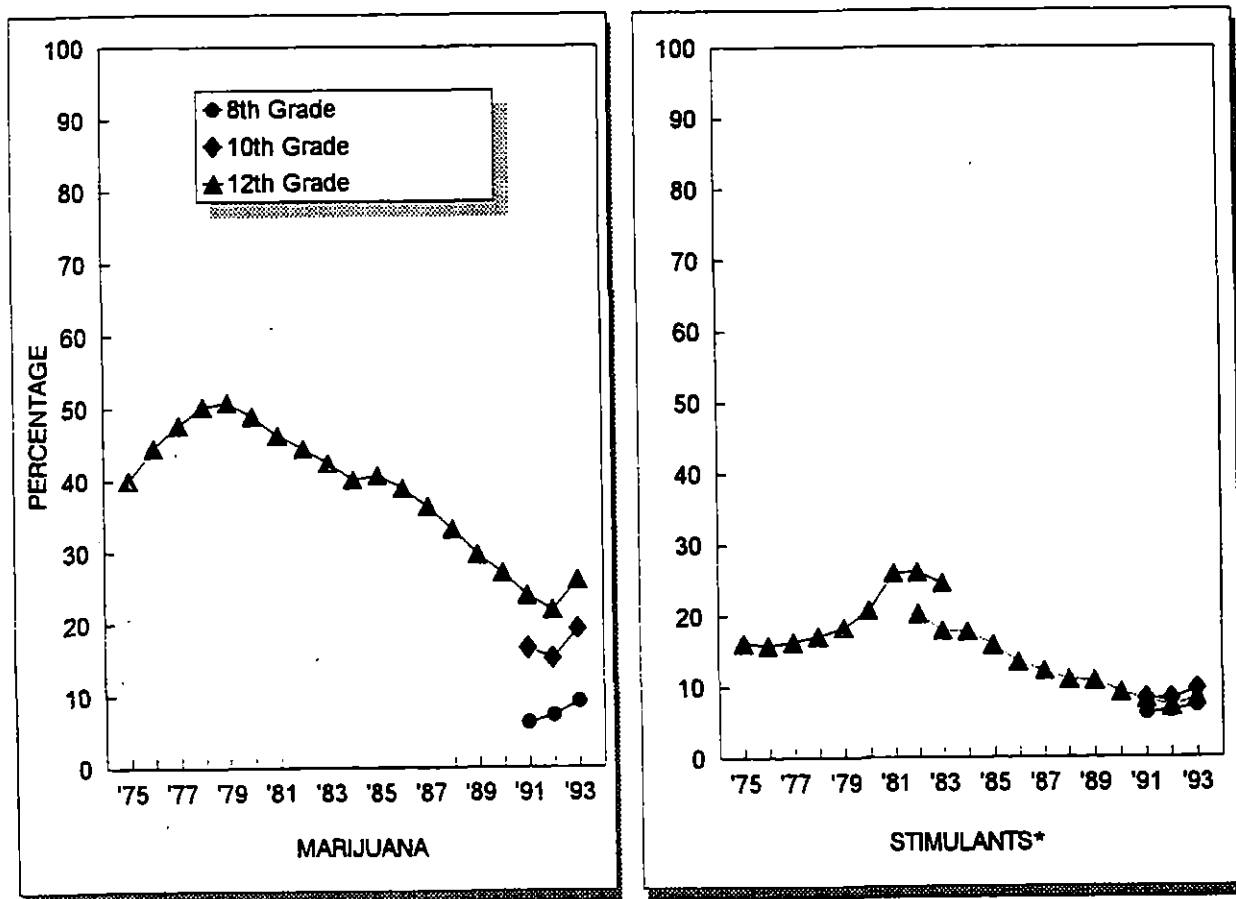

- Although the overall proportion using illicit drugs other than marijuana has changed gradually and steadily over the years, greater fluctuations have occurred for specific drugs within the class. This is important because it shows that, while the proportion willing to try any illicit drug may put outer limits on the amplitude of fluctuations for any one of them, the various subclasses of drugs must have important determinants specific to them—variables such as perceived risks, peer normative attitudes, assumed benefits, and availability. Such variables will be discussed in chapters 8 and 9. (See Tables 11 through 13 and Figures 9a through 9h for trends in lifetime, annual, and monthly prevalence for each class of drugs.)
- From 1976 to 1979 *cocaine* (Figure 9e) exhibited a substantial increase in popularity, with annual prevalence going from 6% in the class of 1976 to 12% in the class of 1979—a two-fold increase in just three years. For the nation as a whole, there was little or no change in any of the cocaine prevalence statistics for seniors between 1979 and 1984. (Subgroup differences in trends are discussed below.) In 1985, we reported statistically significant increases in annual and monthly use, then a leveling again in 1986. However, since 1986 both indicators of use have decreased substantially: annual use decreased from 12.7% in 1986 to 3.1% in 1992; monthly use decreased from 6.2% to 1.3% over the same period—nearly an 80% drop. (Reasons for this decrease are discussed in the chapter on attitudes and beliefs.) The declines ended in 1993, however, with annual prevalence at 3.3% (up 0.2%) and 30-day prevalence at 1.3% (no change).
- Use of *crack cocaine* was first measured in 1986 by a single question contained in one questionnaire form, and asked only of those who reported any use of cocaine in the past 12 months. It simply asked if crack was one of the forms of cocaine they had used. It is thus an estimate of the annual prevalence of crack use.

Other indicators that were gathered routinely in the study show some indirect evidence of the rapid spread of crack prior to 1986. For example, we found that the proportion of all seniors reporting that they smoked cocaine (as well as having used in the past year) more than doubled between 1983 and 1986 from 2.4% to 5.7%; in the same period the proportion of all seniors who said that they both had used cocaine during the prior year and had at some time been unable to stop using when they tried to also doubled (from 0.4% to 0.8%); and, between 1984 and 1986 the proportion of seniors reporting active daily use of cocaine doubled (from 0.2% to 0.4%). We think it likely that the advent of crack use during this period contributed to these statistics.

- In 1987 we introduced questions about crack use into two questionnaire forms using our standard set of three questions which ask separately

*Smokeless tobacco data not available in 1990 or 1991.

about frequency of use in lifetime, past 12 months, and past 30 days. These were added subsequently to all forms beginning in 1990.

Between 1986 and 1992, annual *crack* prevalence declined from 4.1% to 1.5%, or about 60% over this time period (see Figure 9e). Lifetime prevalence rates were 5.4% in 1987 (the first year this measure was available) and were down by half to a low of 2.6% in 1992. The figures for 30-day prevalence have dropped from 1.3% in 1987 to 0.7% in 1990. In the last several years, rates have remained relatively stable.

It is important to note that *crack* use may be disproportionately located in the out-of-school population relative to most other drugs. In general, it would seem likely that the trends there would parallel those seen among high school seniors, who represent the majority of the population the same age, but one could imagine exceptions.

- Like cocaine use, *inhalant* use rose steadily, but more slowly, in the late 1970s (see Figure 9b). Annual prevalence (unadjusted) rose from 3.0% in 1976 and peaked at 5.4% in 1979. Starting in 1979 when separate questions were introduced to measure the rising use of nitrite inhalants, an adjustment was introduced into the overall inhalant use measure to correct for the known underreporting of nitrite inhalants. Between 1979 and 1983, there was some overall decline in this adjusted version—in part due to a substantial drop in the use of *amyl and butyl nitrites*, for which annual prevalence declined from 6.5% in 1979 to 3.6% in 1983. Both the adjusted and unadjusted measures increased modestly between 1983 and 1986, with annual use for inhalants (adjusted) increasing from 6.2% in 1983 to 8.9% in 1986, and the use of nitrites increasing less, from 3.6% to 4.7%.

Since 1986, there has been a steep decline in annual *nitrite* use (from 4.7% to 0.9% in 1993) but only a modest decline in overall inhalant use (adjusted), with annual prevalence falling from 8.9% in 1986 to 6.4% in 1992, then rising to 7.4% in 1993. The gradual convergence of the unadjusted and adjusted inhalant prevalence rates, seen in Figure 9b, suggests that the number of seniors who use nitrites, but do not report themselves as inhalant users on the general inhalant-use question, has diminished considerably, as would be expected in light of the overall decline in nitrite use.

This unusual pattern of change, where inhalant use unadjusted for nitrites rose sharply over most of the life of the study, while the version adjusted for nitrites stayed fairly level over most of the life of the study (Figure 9b) is worth further consideration. Essentially, *inhalants other than the nitrites* have been rising in use, but since 1979 this rise in use was largely offset in the adjusted inhalants measure by the sharp decline in the use of the nitrites. Over time this class of drug-

abusing behavior has become more common. In the class of 1976, when the inhalant questions were first introduced, only 10.3% indicated any lifetime use, vs. 17.4% in 1993—a substantial increase. Annual prevalence more than doubled over the same interval, from 3.0% to 7.0%.

- **Stimulant** (amphetamine) use, remained relatively unchanged between 1975 and 1978, then began to show evidence of a gradual increase in use in 1979, with even greater increases occurring in 1980 and 1981 (Figure 9a). Between 1976 and 1981, reported annual prevalence rose by 10 percentage points (from 16% to 26%); daily use tripled, from 0.4% to 1.2%. As stated earlier, we think these increases were exaggerated—perhaps sharply—by respondents in the 1980 and 1981 surveys in particular including nonamphetamine, over-the-counter diet pills (as well as "look-alike" and "sound-alike" pills) in their answers. In 1982, we added new versions of the questions on amphetamine use, which were more explicit in instructing respondents not to include such nonprescription pills. (These were added to only three of the five forms of the questionnaire being used; the amphetamine questions were left unchanged in the other two forms until 1984.) Between 1981 and 1982 prevalence rates dropped slightly as a result of this methodological change. In Tables 11 through 15, data for 1975 through 1981 are based on the unchanged questions, providing comparable data across time for longer-term trend estimates and data for 1982 through 1993 are based on the revised questions, providing our best assessments of current prevalence and recent trends in true amphetamine use.²¹

In 1982 and 1983, the two years for which both adjusted and unadjusted statistics are available, the unadjusted showed a modest amount of overreporting (see Figure 9a). Both types of statistics, however, suggest that a downturn in the current use of stimulants began to occur in 1982 and continued for a decade. For example, between 1982 and 1992 the annual prevalence for amphetamines (adjusted) fell by six-tenths from 20% to 7%. Current use also fell by more than half. As with a number of other drugs, however, the trend lines veered upwards in 1993. Annual prevalence rose significantly from 7.1% in 1992 to 8.4% in 1993.

- In 1990 questions were added about twelfth graders' use of *ice*, a crystallized form of methamphetamine which can be smoked much like crack. Despite the widespread concern that an epidemic of ice use would develop, it has not made much of an inroad into this population, perhaps because the dangerous reputation of crack rubbed off on it. The peak lifetime prevalence was 3.3% in 1991. It dropped to 2.9% in

²¹ We think the unadjusted estimates for the earliest years of the survey were probably little affected by the improper inclusion of nonprescription stimulants, since sales of the latter did not burgeon until after the 1979 data collection.

Monitoring the Future

1992 and rose again in 1993 to 3.1%. The annual and 30-day prevalence measures have been virtually flat since the first observations were taken in 1990. Annual prevalence now stands at 1.7%.

- The sustained, gradual decline in *sedative* use (Figure 9c) between 1975 and 1979 halted in 1980 and 1981. Annual prevalence, which dropped steadily from 11.7% in 1975 to 9.9% in 1979, increased slightly to 10.5% in 1981. The longer-term decline resumed again in 1982, and over the next decade annual prevalence fell to 2.9%. There was a slight, not statistically significant, increase in all prevalence measures in 1993.

The overall trend lines for sedatives mask differential trends occurring for the two components of the measure. *Barbiturate* use (Figure 9c) declined steadily between 1975 and 1987 before leveling. By 1992 annual prevalence (2.8%) was less than one-third of the 1975 level (10.7%). In 1993, *barbiturate* use rose, but by a non-significant amount. *Methaqualone* use (Figure 9c), on the other hand, rose sharply from 1978 until 1981. In fact, it was the only drug other than stimulants that was still rising in 1981. But in 1982, the use of methaqualone also began to decline, which accounted for the overall sedative category resuming its decline that year. Annual use (0.2% in 1993) now stands at a tiny fraction of its peak level observed in 1981 (7.6%). Because of the very low prevalence rates, methaqualone questions were dropped from five of the six forms in 1990; since then, sedative prevalence estimates, a combination of barbiturate and methaqualone prevalence, are based on only one questionnaire form.

- Usage statistics for *tranquilizers* (Figure 9b) peaked in 1977, probably following a considerable period of increase. Lifetime prevalence dropped by two-thirds (from 18% in 1977 to 6% in 1992), annual prevalence by nearly three-fourths (from 11% to 2.8%), and 30-day prevalence by more than three-fourths (from 4.6% to 1.0%). Following significant declines on all three prevalence measures in 1992, all showed an increase in 1993, with the increase in annual prevalence being statistically significant.
- Between 1975 and 1979 the prevalence of *heroin* use dropped rather steadily (Figure 9f). Lifetime prevalence dropped from 2.2% in 1975 to 1.1% in 1979 and annual prevalence also dropped by half, from 1.0% in 1975 to 0.5% in 1979. This decline halted in 1979 and the statistics have remained almost constant for more than a decade. In 1993, all prevalence rates remain the same as they were in 1979, with very little change in the intervening years.

- For the first twelve years of the study, the use of *opiates other than heroin* remained fairly stable, with annual prevalence fluctuating between 5.1% and 6.4% (see Figure 9f). After 1987 there was a modest, gradual decline in annual prevalence from 5.3% to 3.3% in 1992. In 1993 there was a slight, not statistically significant increase in use.
- *Hallucinogen* use (unadjusted for underreporting of PCP) declined some in the mid-1970s (Figure 9d) from annual prevalence of 11.2% in 1975 to 9.6% in 1978. This may well have been the tail end of a longer period of decline precipitated by rising concerns about the adverse effects of hallucinogens—particularly LSD—and particularly about their possible damage to the brain and to genes. The use of hallucinogens other than PCP then leveled for several years before beginning another sustained decline. Between 1979, when the first figures adjusted for the underreporting of PCP were available, and 1984 there was a steady decline, with the annual prevalence of *hallucinogens, adjusted* dropping from 11.8% to 7.3%. The rate remained fairly level through 1986, dropped a little more through 1988, then remained level again through 1992. In 1993 this pattern of irregular declines ended, as annual prevalence rose significantly from 6.2% to 7.8%.
- *LSD*, one of the major drugs comprising the hallucinogen class, showed a modest decline from 1975 to 1977, followed by considerable stability through 1981 (Figure 9d). Between 1981 and 1985 there was a second period of gradual decline, with annual prevalence falling from 6.5% to 4.4%. However, since 1985 annual prevalence has risen gradually, from 4.4% to 5.6% in 1992. In recent years LSD has been bucking the trends for nearly all illicit drugs, and there also has been some rise in use in the other populations included in this study. The rate of increase accelerated in 1993 as annual prevalence jumped from 5.6% to 6.8%.
- Prevalence statistics for the specific hallucinogen *PCP* have shown a very substantial decline since 1979 when the use of this drug was first measured (see Figure 9d). Annual prevalence dropped from 7.0% in the class of 1979 to 2.2% in the class of 1982. After leveling for a few years, it dropped further to reach 1.3% in 1987, which is about where it has remained in the years since. The speed with which this drug fell from popularity strongly suggests that it got a bad reputation as a dangerous drug very quickly.
- As can be seen from these varied patterns of use, the overall proportion of seniors using *any illicit drugs other than marijuana* in their lifetime has changed some over the years, but the mix of drugs they are using has changed even more. A number of drug classes have shown dramatic declines, some have shown substantial increases, and some have remained fairly stable. Further, the periods in which they either

increased or declined varied considerably for the different classes of drugs.

- Turning to the licit drugs, in the last half of the 1970s there was a small upward shift in the prevalence of *alcohol* use among seniors (see Figure 9g). To illustrate, between 1975 and 1979 the annual prevalence rate rose steadily from 85% to 88%, the monthly prevalence rose from 68% to 72%, and the daily prevalence rose from 5.7% to 6.9%. As with marijuana, 1979 was the peak year for annual use. Since 1979, there has been a slight decrease in lifetime prevalence (from 93% to 87% in 1993) and some drop for the more current prevalence intervals. Between 1979 and 1985 annual prevalence fell from 88% to 86%, monthly prevalence from 72% to 66%, and daily prevalence from 6.9% to 5.0%. (The change in daily use is the most important of these shifts.) All three rates remained fairly level from about 1985 to 1987; since then they have shown some further decline. Thirty-day prevalence, for example, fell from 66% in 1987 to 51% in 1993, and is down by nearly one-third from its peak level in 1978 (72%). The prevalence of daily use fell from 4.8% to 3.4% between 1987 and 1992, followed by a sharper drop to 2.5% in 1993. It is now down by more than one-half from its peak level in 1979 (6.9%).
- A similar pattern was observed in the frequency of *occasional heavy drinking* (Figure 9g). When asked whether they had taken five or more drinks in a row during the prior two weeks, 37% of the seniors in 1975 said they had. This proportion rose gradually to 41% by 1979, where it remained through 1983. In both 1984 and 1985, we observed drops of 2 percentage points in this troublesome statistic, bringing it to 37%, exactly where it was in 1975. There was no further change in 1986 or 1987. Since 1987 it has dropped by another 10 percentage points, from 38% to 28% in 1993—a drop of nearly one-third from its peak level of 41%.

Beginning in 1991, respondents were asked to report how often they had *been drunk* in their lifetime, the past 12 months, and the past 30 days. These measures show declines since 1991, as would be expected given the data above (Tables 11-14).

- There is no evidence that the drop in marijuana use observed over the past 14 years has led to a concomitant increase in alcohol use, as many observers suggested would happen. In fact, through 1992 there was some parallel decline in annual, monthly, and daily alcohol use as well as in occasional heavy drinking.
- 1976 and 1977 were the years of peak *cigarette use* in this age group, as measured by lifetime, 30-day, and daily prevalence. (Annual prevalence is not asked.) Over the four subsequent graduating classes,

30-day prevalence dropped substantially from 38% in the class of 1977 to 29% in the class of 1981. (See Tables 13 and 14 and Figure 9h.) More importantly, *daily cigarette use* dropped over that same interval from 29% to 20%, and daily use of half-pack-a-day or more from 19% to 14% between 1977 and 1981. In 1982 and 1983 the decline had clearly halted. There was a brief resumption of the earlier decline in 1984, with daily use falling from 21% to 19%, and daily use of half-pack-a-day dropping from 14% to 12%. Since 1984, there has been very little change in most of these statistics. From 1984 to 1992, 30-day prevalence fell from 29% to 28%, daily use from 19% to 17%, and half-pack-a-day smoking from 12% to 10%. Despite the general decline which has occurred for most other drugs (including alcohol), the considerable amount of restrictive legislation which has been debated and enacted at state and local levels over those past eight years, and the prevention efforts being made in many school systems, there is a noteworthy lack of any appreciable decline in smoking rates. Matters got worse in 1993, as 30-day and current daily smoking rates both rose significantly (by 2.1 percentage points and 1.8 percentage points, respectively).

- Questions about the use of *smokeless tobacco*, which includes chewing tobacco and snuff, were first introduced in 1986. They were omitted in 1990 and 1991, then reintroduced in 1992. The results show a high rate of use for the sample overall, and it is particularly high for the boys, who account for nearly all of the use. In 1993 about one-third of all seniors had tried smokeless tobacco and 3.3% were current daily users. The trends for the period 1986 to 1989 showed a decline in use, with 30-day prevalence falling steadily from 11.5% to 8.4%. When the questions were reintroduced in 1992, the rate had returned almost to its 1986 level (11.4%), and is now down to 10.7% in 1993 (not a statistically significant change). The fact that these questions are in a single questionnaire form means that the estimates are based on smaller samples than is true for most drugs. It is thus quite possible to conclude that the usage level since 1986 has really been fairly flat, with random fluctuations in samples accounting for the apparent changes.
- Trend data on *steroid* use are available since 1989. Annual prevalence declined gradually, but steadily, from 1.9% in 1989 to 1.1% in 1992, before leveling in 1993.

TRENDS IN PREVALENCE 1991-1993: EIGHTH AND TENTH GRADERS

Trend data for all three grades (8, 10, and 12) are included in Table 15 to facilitate cross-grade comparisons.

^a12th grade only: Data based on five questionnaire forms. N is five-sixths of N indicated.

^b12th grade only: Unadjusted for underreporting of certain drugs.

^c12th grade only: Data based on four questionnaire forms. N is four-sixths of N indicated.

^d12th grade only: Only drug use which was not under a doctor's orders is included here.

^e1993 only: Data based on one of two questionnaire forms for 8th and 10th grades and on three of six questionnaire forms for 12th grade. N is one-half of N indicated.

^f12th grade only: Data based on two questionnaire forms. N is two-sixths of N indicated.

^gData based on one questionnaire form. N is one-half of N indicated for 8th and 10th grades, and N is one-sixth of N indicated for 12th grade.

Monitoring the Future

- In the previous volume in this series, we noted that the trends for 1991-1992 were different for the three grade levels on a number of drugs. In 1993, however, the three grades moved in parallel, which meant that they all showed increases in their use of a number of drugs.
- **Marijuana use** continued to rise among eighth graders, with annual prevalence up from 6.2% in 1991 to 7.2% in 1992, and to 9.2% in 1993—about a one-half increase in two years. Use rose among tenth and twelfth graders, as well, from 15.2% to 19.2% for the former and from 21.9% to 26.0% for the latter. There were large proportional changes in 30-day and daily marijuana use at all grade levels, as well. In sum, there was a clear and important turnaround in the situation (see Table 15).
- Annual **hallucinogen** use already had begun rising among eighth graders by 1992. In 1993 tenth and twelfth graders also increased with the largest increase in twelfth grade. This pattern was closely followed by the two components of the hallucinogens class, **LSD** and **hallucinogens other than LSD**. (Table 15.) Note also that LSD currently accounts for most of the hallucinogen use at all grade levels.
- The increase in **LSD** use is of particular interest because LSD was one of the first drugs to decline in the long-term epidemic, almost surely due to growing concerns about its dangers in the early to mid-1970s. It therefore may be the first to reflect the effects of "generational forgetting," where replacement cohorts do not have as much concern about its dangers as their predecessors because they did not have comparable opportunities for direct and vicarious learning about the consequences of using the drug.²²
- Having risen a bit among eighth graders in 1992, **cocaine** showed rather little change in any of the three grades in 1993. Nor was there much change in 1993 in either of the component classes, **crack** and **other cocaine**, though some of the findings on attitudes and peers to be presented below, provide the basis for some concern about the future.
- **Stimulants** constitute another class of drugs which was very popular early in the epidemic. They also showed an increase in use in all three grade levels in 1993, reaching annual prevalence rates of 7.2% for eighth graders, 9.6% for tenth graders, and 8.4% for twelfth graders. As with several other drugs, the rise in use appears to have begun a year earlier among the eighth graders.

²²See Johnston, L.D. (1991). Toward a theory of drug epidemics. In R.L. Donohew, H. Sypher, & W. Bukoski (Eds.), *Persuasive communication and drug abuse prevention* (pp. 93-132). Hillsdale, NJ: Lawrence Erlbaum.

- While not all of the *inhalant* changes reach statistical significance, all three prevalence measures rose in all three grade levels in 1993. In the case of the annual prevalence statistics, this was the second year of increase for the eighth and tenth graders. Recall that the twelfth graders showed a considerable long-term increase in inhalant use over the past decade or so, and it seems likely that a parallel trend may have been happening in the lower grades, as well.
- *Tranquilizer* use did not show a consistent pattern of change across grades either in 1992 or 1993.
- There has been no systematic change in *heroin* use since 1991 at any grade level.
- With regard to *alcohol*, since 1991 the lifetime and annual prevalence measures have shown some decline in all three grades. However, the 30-day prevalence measures have not declined among eighth graders, declined rather little among tenth graders, but have shown a three percentage point decline among twelfth graders. Even among twelfth graders, however, there was little change between 1992 and 1993, perhaps signaling the end of the decline.

Daily drinking declined only among seniors, continuing a longer-term trend. There was rather little change in 1993 in the self-reported *drunkenness* or *binge drinking* rates, except for an increase among tenth graders which offset a decrease the prior year.

- *Cigarettes* can be expected to move less synchronously across the three grade levels because changes are usually the result of cohort effects rather than secular trends, and this was the case in 1992. However, in 1993 all three grade levels showed a significant increase in daily smoking. Because of this parallel movement, we are inclined to look for some historical correlate, and one clear possibility is that cigarette prices dropped on average because of increased price competition among brands.
- Among eighth graders, lifetime prevalence of *smokeless tobacco* fell significantly for the second year in a row. However, in none of the grades was there an appreciable change in current use.
- *Steroid* use showed little change in any grade level in either 1992 or 1993.

TRENDS IN NONCONTINUATION RATES: TWELFTH GRADERS

Table 16 shows how the user noncontinuation rates observed for the various classes of drugs have changed over time among twelfth graders. (No such calculations have yet been made for the lower grades.) Recall that the noncontinuation rate is defined here as the percentage of those who ever used the drug but did not use in the twelve months prior to the survey.

- **Marijuana** showed some increase in the noncontinuation rates between 1979 (16%) and 1984 (27%). This increase gave rise to the greater drop in annual use than in lifetime use. Between 1984 and 1987 there was no further increase, followed by a rise to 35% in 1991. The noncontinuation rate then fell sharply to 26% by 1993, which helps to explain the sharp turnaround in the prevalence rates.
- The noncontinuation rate for **cocaine** decreased from 38% in 1976 to 22% in 1979, corresponding to the period of increase in the overall prevalence of use. It then remained fairly stable through 1986, corresponding to a period of stability in the actual prevalence statistics. Since 1986, use has fallen substantially, reflecting in part a considerable increase in the rate of noncontinuation—from 25% in 1986 to 55% in 1991. By 1993, there was a decline to 46%.
- For **crack**, statistics exist only since 1987, but they also show a sharp rise in noncontinuation, from 28% in 1987 to 52% in 1991. Since then, the noncontinuation rate fell to 42%.
- There was considerably more noncontinuation of **stimulant** use in 1993 (44%) than in 1982 (27%). Earlier data (based on the unrevised questions) suggest that the change began after 1981.
- Much of the recent decline in **sedative** use is also accounted for by a changing rate of noncontinuation for the specific substances involved. For example, in the case of **barbiturates** the noncontinuation rate rose from 36% in 1979 to 49% in 1992. Similarly in 1980, 24% of the seniors who ever used **methaqualone** did not use in the prior year, but by 1993 that figure was up to 75%.
- **Tranquilizer** users showed a steady, gradual increase in their noncontinuation rates between 1975 and 1982, from 38% to 50%. Then until 1992, there was little further systematic change. In 1993, though, there was a decline, from 53% to 45%.
- For **LSD** the noncontinuation rate has fluctuated within a rather narrow range (between 34% and 41%) since 1981, without any clear trending.

*Percentage of regular users (ever) who did not use at all in the last thirty days.

Monitoring the Future

- After 1987 there had been a slight increase in the noncontinuation rate for *smokeless tobacco*, but it did not continue into 1993.
- *Steroid* use appears to have had an increase in noncontinuation in 1992, a year in which there was an increase in the perceived dangers of using steroids, but the rate dropped back some in 1993.
- It is worth noting that, although *alcohol* has always had an extremely low rate of noncontinuation, that rate has been increasing gradually in recent years, likely reflecting the changed norms regarding its use (see Chapter 8) which in turn may reflect the impact of changing the drinking age laws in a number of states.
- Table 17 provides noncontinuation rates for seniors who were more established users—that is, for those who reported having used the drug ten or more times in their life. It shows that noncontinuation is far less likely among such heavier users than among all users of a given drug. Further, while the trends in noncontinuation mentioned above for *marijuana, cocaine, stimulants, barbiturates, and tranquilizers* are all similar to trends observed in the noncontinuation rates for heavier users of those same drugs, the percentage fluctuations tend to be considerably smaller among the heavier users.

The reader is cautioned that the number of cases in each cell in Table 17 is considerably smaller than in most other tables—particularly when overall usage rates are low to start with; therefore the trend data are much more uneven.

- Note that noncontinuation rates for experienced users of *inhalants* actually dropped in the late 1970's, perhaps as a result of the nitrites—which are used at older ages than most of the other inhalants—coming onto the scene. However, when the nitrites left the scene during the 1980s, the noncontinuation rates for experienced users failed to increase.
- Note the sharp rise in the late 1980s in the noncontinuation rates for *cocaine* and *crack*, even among these more experienced users. The rates peaked by 1991, though, and have fallen back considerably since.

COMPARISONS AMONG SUBGROUPS IN TRENDS IN PREVALENCE: TWELFTH GRADERS ONLY

Trend comparisons are given below for population subgroups defined on the following dimensions: gender, college plans, region of the country, population density, racial/ethnic

*The cell entries in these rows were omitted because they were based on fewer than 50 seniors who used ten or more times. All other cells contain more than 50 cases.

^bBased on 85 cases in 1987, 54 cases in 1988, and 56 cases in 1989. Crack was included in all six questionnaire forms in 1990-1993.

^cBased on too few cases in 1990-1993, because this question was asked in only one of the six questionnaire forms.

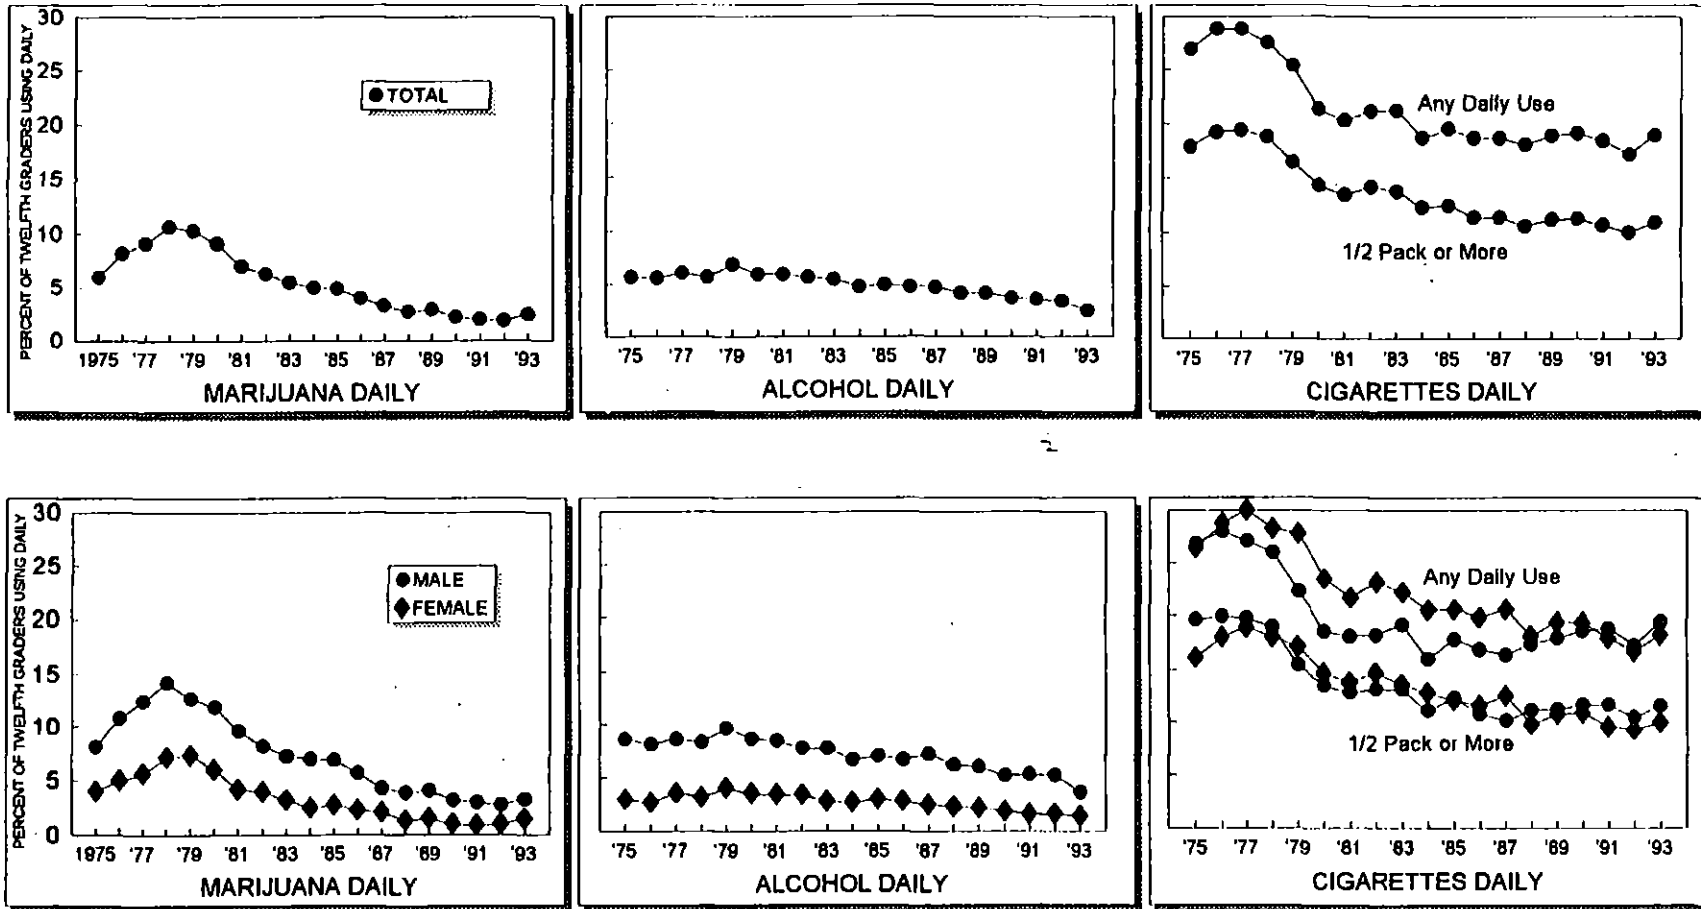

Monitoring the Future

group, and socioeconomic status. In general, only the results from twelfth graders will be discussed, because there is such a short trend interval available to date for eighth and tenth graders.

Sex Differences in Trends

- Most of the sex differences mentioned earlier for individual classes of drugs have remained relatively unchanged over the past nineteen years—that is, any trends in overall use have been fairly parallel for both males and females. There are, however, some exceptions (tabular data not shown).
- The absolute differences between the sexes in *marijuana* use narrowed somewhat between the 1970s and 1980s, although both sexes saw a similar decline in use from 1979 to 1992. Both sexes also showed an increase in marijuana use in 1993.
- Between 1975 and 1977 there was a small sex difference in *tranquilizer* use (females this age had used them more frequently than males). This difference virtually disappeared by 1978, and there has been no sex difference since.
- The sex differences in *cocaine* use were greatest in the peak years of use (1979 through 1986) and diminished considerably during the decline phase. Although the differences have lessened, males still use more frequently than females. Males also continue to have higher rates of *crack* use, but the difference has narrowed some since 1988.
- Regarding *stimulant* use, a sex difference emerged in 1981 and 1982 using the original version of the question; but the revised question introduced in 1982 showed no sex difference, suggesting that over-the-counter diet pills accounted for the higher use among females in those two years. Since 1982 the rates for the two sexes have remained very close with both sexes showing a substantial decrease in use through 1992, and both showing an increase in use in 1993.
- Sex differences in the use of *opiates other than heroin* have narrowed in recent years to the point of little or no difference. (Males have almost always had higher rates of use.)
- The proportion of males who used *any illicit drug* in the prior year rose between 1975 and 1978, and then declined steadily to 29% in 1992 (see Figure 12). Use among females peaked later, increasing from 41% in 1975 to 51% in 1981 and then dropped to 25% in 1992. (If amphetamine use is not included in the statistics, use by females peaked earlier [in 1979] and then declined as well.) Both male and female rates were up in 1993, to 34% and 28%, respectively. The

FIGURE 10
Trends in Thirty-Day Prevalence of Daily Use of
Marijuana, Alcohol, and Cigarettes for Twelfth Graders
by Total and by Sex

NOTE: Daily use for alcohol and marijuana is defined as use on 20 or more occasions in the past thirty days. Daily use of cigarettes is defined as smoking one or more cigarettes per day in the past thirty days.

FIGURE 11

**Trends in Two-Week Prevalence of Heavy Drinking Among Twelfth Graders
by Sex**

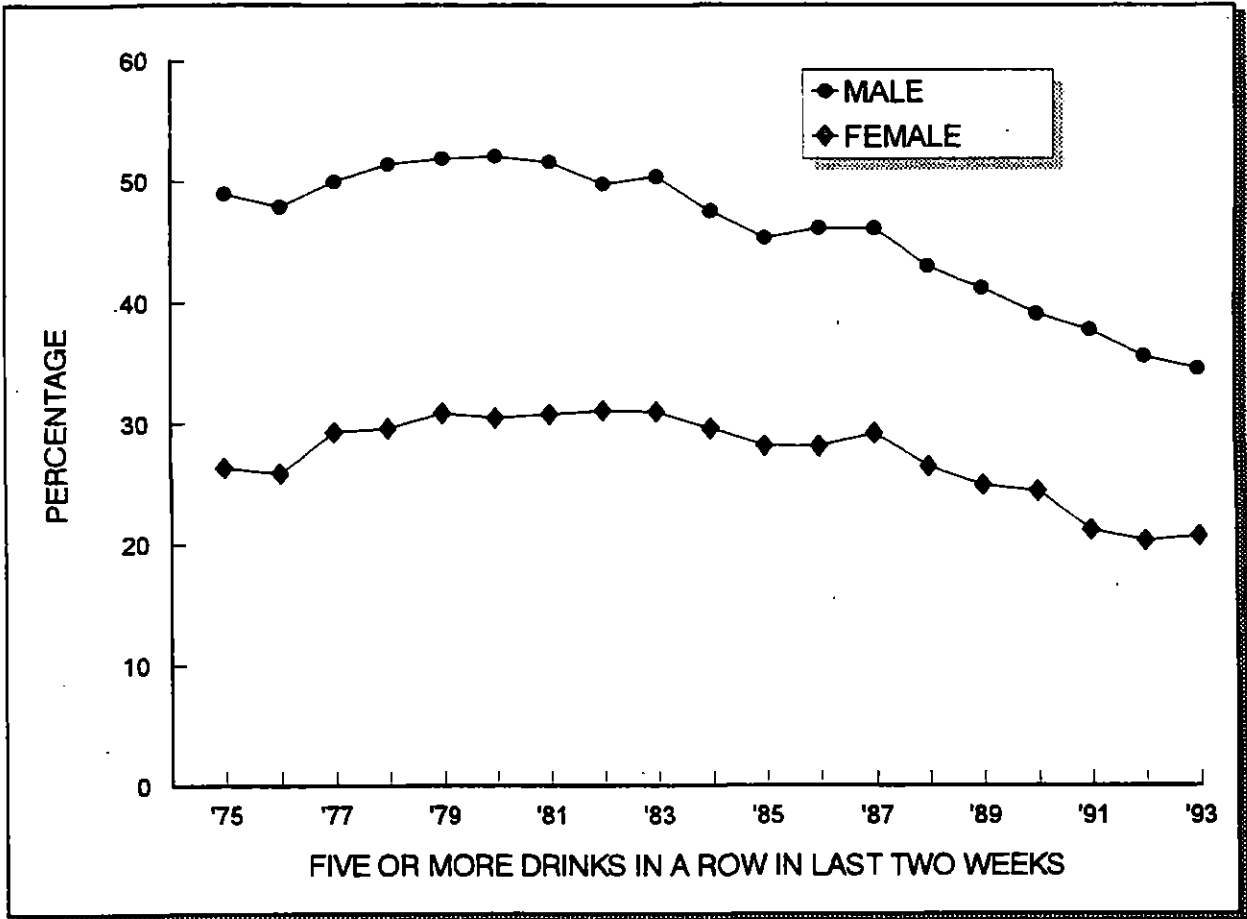

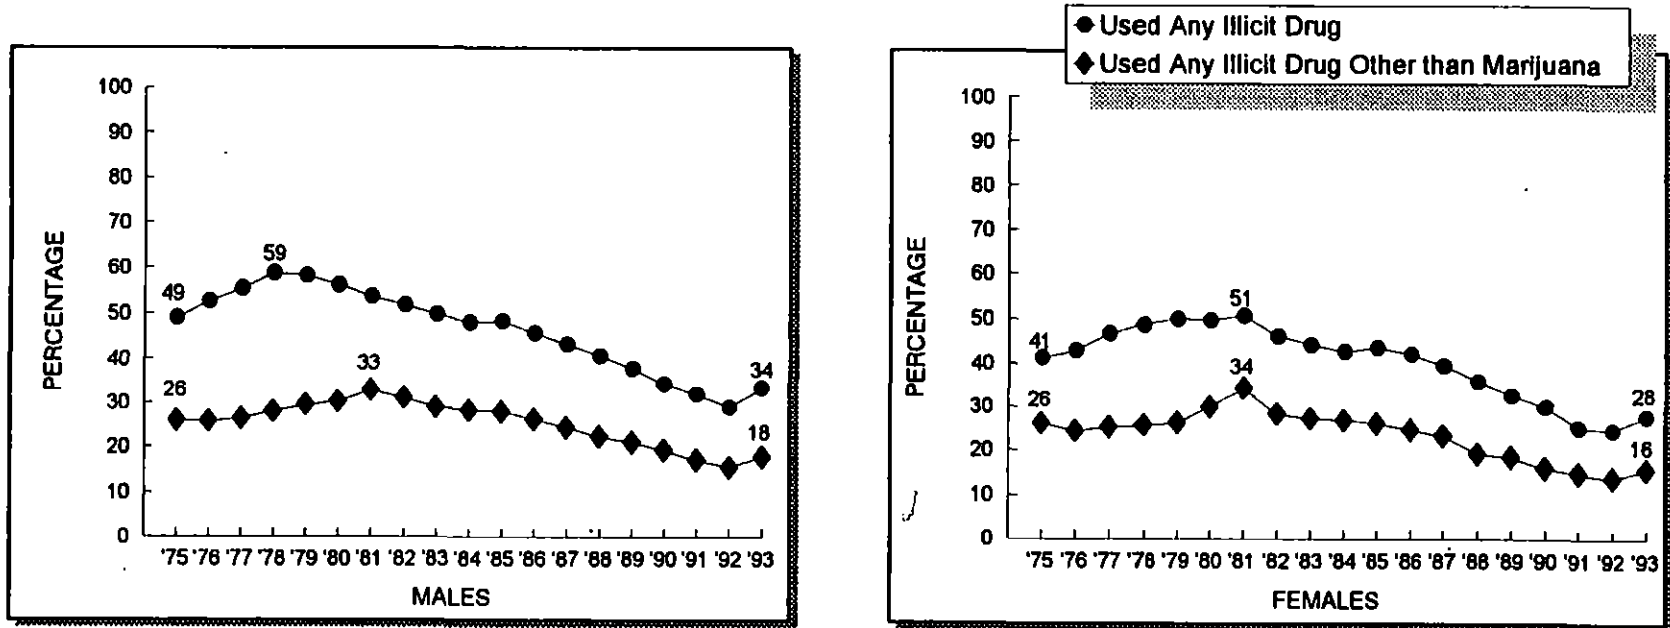

FIGURE 12

Trends in Annual Prevalence of an Illicit Drug Use Index for Twelfth Graders by Sex

NOTE: See Figure 8 for relevant footnotes.

earlier declines for both sexes were attributable largely to the declining marijuana use rates; the later declines (through 1992) were due to decreases in use of the other illicit drugs (primarily cocaine), in addition to marijuana.

- Regarding the apparent parity between the sexes in the levels and trends in the prevalence of use of *illicit drugs other than marijuana*, when amphetamine use is excluded from the calculations, somewhat differential levels emerge for males vs. females (males are higher), although the trends tend to remain fairly parallel.
- The sex differences in *alcohol* use have narrowed slightly since 1975. For example, differences in annual prevalence (males were higher) have been nearly eliminated. The 30-day prevalence rates for males and females differed by 12.8% in 1975 (75.0% vs. 62.2%, respectively), but that difference was down to 8.2% by 1993 (54.9% vs. 46.7%). Although substantial sex differences in *daily use* and *occasions of heavy drinking* still remain, differences have narrowed there, too (Figure 11). For example, between 1975 and 1992 the proportion of males admitting to having five drinks in a row during the prior two weeks showed a net decrease of 14 percentage points (49% to 35%), whereas females decreased by only 5 percentage points, from 26% to 21%.²³
- On one of the six questionnaire forms administered to the twelfth graders, respondents are asked separately about their use of beer, wine, and hard liquor. The answers to these questions reveal that different rates of beer consumption account for much of the large sex differences in occasions of heavy drinking: 34% of 1993 senior males report having *five or more beers* in a row during the prior two weeks vs. 18% of the females. Males are also somewhat more likely than females to report having *five or more drinks of hard liquor* (25% for males vs. 13% for females) but only slightly more likely to drink *wine* that heavily (7% for males vs. 4% for females). This pattern—a large sex difference in heavy use of beer, a smaller difference in heavy use of hard liquor, and very little difference in heavy use of wine—has been present throughout the study, with little systematic change over time. (It might be noted that in 1993 the heavy use of hard liquor by males jumped considerably, though there was no comparable jump among females.) More recently questions on *wine coolers* were added; 7% of the males and 10% of the females drank five or more in a row in the past two weeks.

²³It is worth noting that the same number of drinks produces substantially greater impact on the blood alcohol level of the average female than the average male, because of sex differences in the metabolism of alcohol and body weight. Thus, sex differences in frequency of actually getting drunk may not be as great as the binge drinking statistics would indicate, since they are based on a fixed number of drinks.

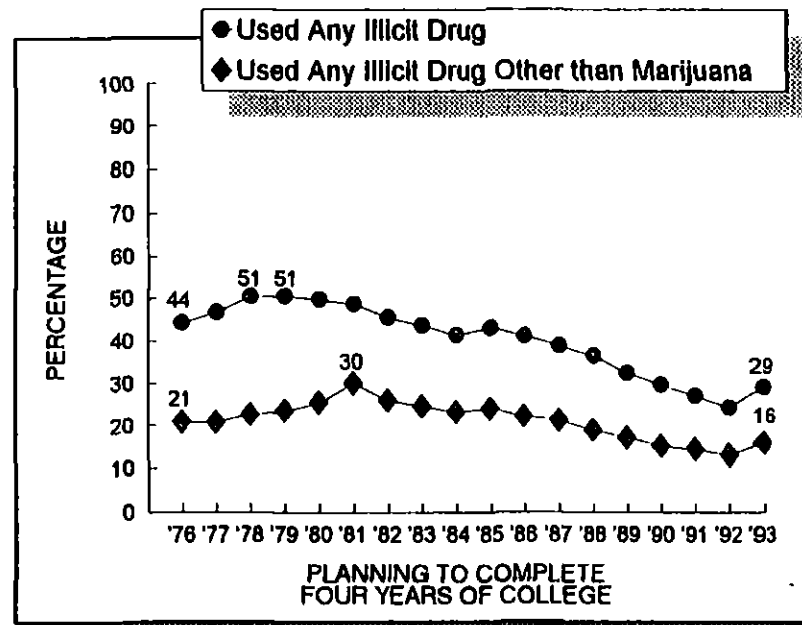

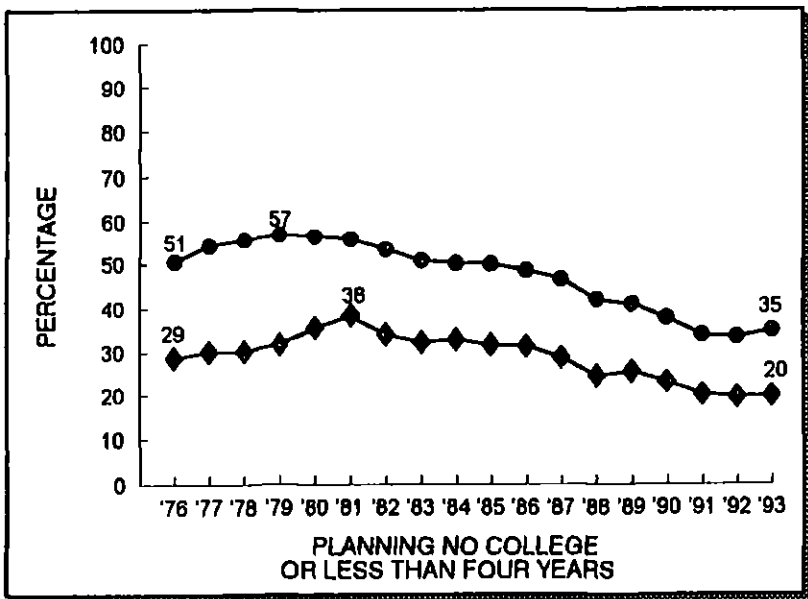

- In 1976 we observed that, for the first time, females caught up to males in **daily cigarette smoking** (see Figure 10). Then, between 1977 and 1981, both sexes showed a decline in the prevalence of such smoking; but use among males dropped slightly more, resulting in females having a higher rate of daily smoking until 1990. For the last three years (1991-1993), males' smoking rates have been very slightly higher than females'.

Trend Differences Related to College Plans

- Both college-bound and noncollege-bound students have been showing fairly parallel trends in overall **illicit drug use** over the last several years (see Figure 13).²⁴ In 1993, there was a sharper increase in use of any illicit drug among the college-bound twelfth graders.
- Changes in use of the **specific drug classes** have also been generally quite parallel for the two groups since 1976, with only minor exceptions (data not shown). Between 1983 and 1986 annual **cocaine** use increased very little among the college-bound, but rose by about one-quarter among the noncollege-bound, perhaps due to the greater popularity of crack among the noncollege-bound. Since 1986 both groups have shown large declines in use, and some convergence in their rates of use.
- In fact, as the overall prevalence of a number of drugs fell through 1992 there was some convergence of usage rates between the college-bound and noncollege-bound, due to a greater drop among the latter group. This was true for **tranquilizers, sedatives, methaqualone, stimulants, barbiturates, nitrite inhalants, hallucinogens other than LSD, LSD, and opiates other than heroin.**
- It is worth noting that the nonsignificant rise in annual prevalence for **LSD** in 1992 was due entirely to a rise among the noncollege-bound. In 1993, the noncollege-bound held steady while a sharp increase occurred among the college-bound, once again narrowing the gap between them. In the two lower grades, most of the increase in LSD use between 1991 and 1993 occurred among the noncollege-bound.
- There has been a modest convergence of the **binge drinking** rates of the two groups since 1981, though the rate for the college-bound is still considerably lower.
- Until 1993, there had been little convergence of the widely disparate rates of **cigarette smoking**. In 1993, though, significant increases in

²⁴Because of excessive missing data in 1975 on the variable measuring college plans, group comparisons are not presented for that year.

FIGURE 13
Trends in Annual Prevalence of an Illicit Drug Use Index for Twelfth Graders
by College Plans

NOTE: See Figure 8 for relevant footnotes.

30-day and daily use among the college-bound seniors narrowed the differences. (The increases were 1.6 and 3.0 percentage points, respectively, for the college-bound; the noncollege-bound showed slight decreases in both measures.)

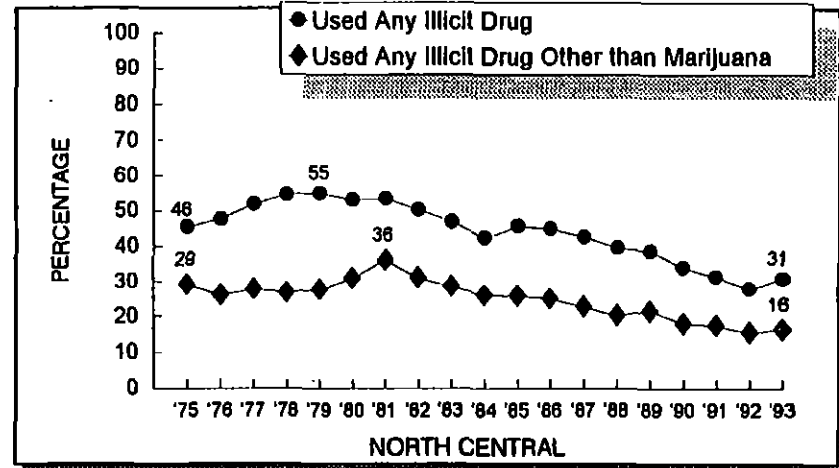

- **Steroid** use has declined in both groups since 1989 when it was first measured.

Regional Differences in Trends

- In all four regions of the country proportions of seniors using **any illicit drug** during the year reached their peaks in 1978 or 1979 (Figure 14a), and generally fell.
- As noted, a major factor in the early rise of **illicit drug use other than marijuana** was an increase in reported **amphetamine** use. The rise in amphetamine use appeared in all four regions; however, the rise in lifetime prevalence from 1978 to 1981 was only 6% in the South, whereas in the other regions the percentages all had risen between 9% and 12%. In essence, the South was least affected by both the rise and the fall in reported amphetamine use. (After 1981 all four regions showed substantial declines until 1993, when they all showed an increase.) Then around 1984 and 1985, when the cocaine and crack epidemics were at their peaks, it was the Northeast and the West which were most affected and showed some increase on this illicit drug use index.
- Over the longer term, **cocaine** use has shown very different trends in the four regions of the country leading to the emergence of one of the largest regional differences observed for any of the drugs (see Figure 14b for differences in lifetime prevalence trends). In the mid-1970s, there was relatively little regional variation in cocaine use. But large regional differences emerged as the nation's cocaine epidemic grew. By 1981 annual use had roughly tripled in the West and Northeast; nearly doubled in the North Central; and increased "only" by about 30% in the South. This pattern of large regional differences held for about six years, until a sharp decline in the Northeast and the West substantially reduced them. In 1993 the West showed a small increase in cocaine levels at all three grade levels; the other regions were stable for the most part.
- Since **crack** use was first measured in 1987, its use has dropped in all four regions, but most in the West, which started out considerably higher than the other regions. Today little regional difference remains although the West still has the highest rate of use.

FIGURE 14b

**Trends in Lifetime Prevalence of Cocaine Use for Twelfth Graders
by Region of the Country**

Monitoring the Future

- All four regions showed an upturn in *marijuana* use in 1993.
- Between 1975 and 1981, sizeable regional differences in *hallucinogen* use emerged, as use in the South dropped appreciably. In 1981, both the North Central and the West had annual rates that were about two and one-half times higher than the South (10.3%, 10.4%, and 4.1%, respectively) and the Northeast was three times as high (12.9%). After 1981, hallucinogen use dropped appreciably in all regions except the South (which continued to be lowest), considerably reducing these regional differences. Use of *LSD*, and *hallucinogens other than LSD* increased in all regions in 1993.
- Between 1979 and 1982, *PCP* use dropped precipitously in all regions, though the drop was greatest in the Northeast which in 1979 had a usage rate roughly double that of all the other regions. In general, PCP use has remained low since 1982 (and without much regional difference).
- All four regions have shown a decline in current *alcohol* use and in occasions of *binge drinking* since the early 80's.
- It is noteworthy that in 1993—a year of overall increase in cigarette smoking—the West was the only region of the four which did not show an increase in *daily smoking* in twelfth grade. The lack of increase in the West may be due to the fact that California has had major anti-smoking campaigns underway in recent years.

Trend Differences Related to Population Density

- Proportions of seniors using *any illicit drug* in all three levels of community size peaked in 1979 (Figure 15a). Although the smaller metropolitan areas and the nonmetropolitan areas never caught up completely with their larger counterparts in their peak levels, they did narrow the gap in usage levels almost completely. Most of that narrowing was due to changing levels of marijuana use, and most of it occurred prior to 1978. All three levels of community size increased in 1993.
- The overall proportion of twelfth grade students involved in *illicit drug use other than marijuana* also peaked in communities of all sizes in 1981 or 1982. Up to 1981, proportions reporting the use of some illicit drug other than marijuana in the last 12 months increased over a four-year period in the very large cities, and over a three-year period in the smaller metropolitan and nonmetropolitan areas. Almost all of this increase is attributable to the rise in reported amphetamine use (which likely is artifactual in part). Between 1983 and 1992 there was a fair-sized decline in all three groups in the use of illicit drugs

FIGURE 15a

by Population Density

NOTE: See Figure 8 for relevant footnotes.

FIGURE 15b

Trends in Annual Prevalence of Alcohol, Marijuana, and Cocaine Use for Twelfth Graders
by Population Density

other than marijuana—again largely attributable to changes in amphetamine use and later to changes in cocaine use. In recent years the large metropolitan areas actually showed slightly lower rates than the other two strata—a reversal of earlier differences. In 1993, all three levels increased slightly.

- During the years in which use of various drugs increased, significant differences among the three levels of urbanicity in use of a number of classes of drugs emerged. In more recent years, those differences narrowed, as use rates declined. Figure 15b shows the trends for annual prevalence of alcohol, marijuana, and cocaine.
- The increase in *cocaine* use between 1976 and 1979, although dramatic at all levels of urbanicity, was clearly greatest in the large cities. Between 1980 and 1984, use was fairly stable in all groupings, and in 1985 they all showed a rise in annual prevalence. In 1986 they all stabilized again, and in 1987, began a decline. Just as the earlier rise had been greatest in the large cities, so was the decline (see Figure 15b). Today there are only small differences by urbanicity in cocaine use among seniors.
- Use of *crack* has declined more among the large cities than in the smaller areas. Since 1986, when it was first measured, annual use is down by 4.6% (from 5.9% to 1.3%) in the large cities, and is down 1.7% (to 1.8%) and by 2.1% (to 1.4%) in the other cities and nonmetropolitan areas, respectively.
- There is evidence of a decline in current *alcohol* use in the large cities in recent years—one which has narrowed the differences considerably. For example, 30-day prevalence in the large cities was down by 29 percentage points, from 78% in 1980 to 49% in 1992, before rising to 52% in 1993. The smaller metropolitan areas decreased 21 percentage points (from 71% to 50% in 1993) and the nonmetropolitan areas dropped by 17 percentage points (from 69% to 52% in 1993). There was no increase in 1993 for the latter two groups.
- In the late 1970s *PCP* use was correlated with community size, but since 1981 there has been no consistent relationship.
- *Marijuana* use also showed a convergence among the three urbanicity groups by 1989 (Figure 15b). Use consistently has been correlated positively with community size. The greatest differences occurred in one of the peak years of usage, 1978. After that both the absolute and proportional differences diminished through 1992 and the more urban areas exhibited a greater decline. In 1993 communities in all size categories showed a turnaround in marijuana use; in fact, the turnaround began a year earlier in the non-metropolitan areas.

Monitoring the Future

- In the last half of the 1970s, the use of *opiates other than heroin* was consistently highest in the large metropolitan areas and lowest in the nonmetropolitan areas. In recent years there has been no consistent difference among these groups.
- The remaining illicit drugs show little systematic variation in trends related to population density.

Differences in Trends by Socioeconomic Status

The measure of socioeconomic status used in this study—namely, the average educational attainment level of the respondents' parents—was described in the previous chapter. Five different strata are distinguished and the students in each graduating class are sorted into those strata based on the educational level of their parents. It should be noted that the overall average educational level of parents of each graduating class has been rising, thus each of the five categories contains a slowly changing proportion of the sample. Figures 16a through 16f show trends for six selected measures of drug use.

- In general there has been little change over time in the relationship between the socioeconomic status (SES) of the family of origin and prevalence rates for most of the drugs.
- *Marijuana* use, for example, has had little association with socioeconomic level throughout the life of the study, except that the lowest level of SES has consistently had a slightly lower prevalence rate. (This may in fact be due as much to a difference in the ethnic composition of this stratum, as we will see in the next section, than to social class differences.) All levels have shown similar declines in use since the late 1970's (Figure 16a), and all levels increased in use in 1993.
- *Cocaine* has shown what is perhaps the largest and most important change in its association with socioeconomic status (Figure 16b). From 1975 through 1981 a strong positive association evolved between cocaine use and SES, with the greatest increase in use occurring in the highest SES group and the least increase in the lowest SES group. From 1981 to 1985 there then followed a decline in use in the top SES levels, while in the lowest SES group there was a substantial increase in use between 1982 and 1985—an increase which may have reflected the introduction of the less expensive form of cocaine, crack.

The net effect has been that, since 1985, there has been no systematic association between overall cocaine use and socioeconomic status. The strong positive association which existed for roughly eight years disappeared. All SES levels showed a substantial decrease in cocaine use between 1986 and 1991, with little differential change since then.

- Except for the fact that the lowest SES group has consistently been a bit lower in its use of *LSD* than the four other strata, there has been little association between SES and the use of this drug over the interval from 1975, when the study began, through about 1984 (Figure 16c). As the overall usage level began to increase gradually after 1984, a positive association has emerged, such that the highest SES group is now almost twice as likely as the lowest SES group to have used LSD in the prior twelve months. Put another way, much of the increase in use which has occurred since 1984 is concentrated in the highest SES groups. All five SES levels showed an increase in LSD use in 1993.
- For a number of drugs there has been little association with SES, and all SES strata have moved in parallel (data not displayed). These include *barbiturates*, *tranquilizers*, *PCP*, and *crack*.
- There has been little difference across the five SES categories in reported use of *inhalants* (data not shown) although the top two categories have tended to have the highest prevalence rate in recent years, and the bottom category to have the lowest. All strata have shown parallel increases since 1983.
- There has been little difference among the SES groups in their trends in *amphetamine* use, but there have been some slight changes. In recent years (1991 through 1993), the two highest SES groups have the lowest rates of amphetamine use. In earlier years (1976 through 1990), there was usually a curvilinear relationship, with the two lowest and the highest SES groups tending to be low in amphetamine use (Figure 16d). The 1993 increase in amphetamine use showed up in all social strata.
- The picture for *alcohol* use is similar to the one described earlier for marijuana: that is, there is little difference in the annual prevalence rates among the SES strata except that the lowest stratum has a lower prevalence than all the others; and they all move pretty much in parallel (data not displayed). The story for *binge drinking* is similar (Figure 16e).
- From 1981 through 1985, *daily use of cigarettes* was ordinarily and inversely related to SES, with each successively higher SES group smoking less (Figure 16f). Beginning in 1986, this ordinal relationship has held with only one exception. In the lowest SES group smoking has declined more than in the other groups, probably due to its racial composition, as will be discussed in the next section. The net result has been that the SES differences have narrowed since 1987.

Racial/Ethnic Differences in Trends

While the three major racial/ethnic groups examined here—whites, blacks, and Hispanics—have quite different levels of use of some drugs, it appears that for almost all drugs, their use has trended in similar ways.²⁵ Data have been examined here for these three groups using two-year moving averages in annual prevalence in order to provide smoother and more reliable trend lines. Even then, they tend to be a bit "bumpy," especially for Hispanics for whom we have the least data and for whom there is a high degree of clustering by school in the sample.

- Figure 17a shows the trends in annual *marijuana* use for the three groups, and illustrates that they have generally moved in parallel—particularly during the long decline phase. In 1993 all three groups showed a rise in marijuana use, with the exception of Hispanics in twelfth grade who had shown an increase in the two prior years.
- Figure 17a also shows the trends for annual *cocaine* use. It shows quite clearly that the rise in cocaine use occurred much more sharply among whites and Hispanics than among blacks. The decline among blacks appears to have begun earlier but, of perhaps greatest importance, all three groups have participated in the sustained decline in cocaine use since 1986. Hispanics showed a very slight rise in 1993 in their use of cocaine other than crack in both eighth and twelfth grades, while use elsewhere was level.
- The rise in reported *inhalant* use (unadjusted for the underreporting of nitrites) occurred about equally in whites and Hispanics from 1975 through 1985, whereupon whites kept rising and Hispanics declined. (Data not shown.) From 1988 to 1992 Hispanics largely closed the gap, however, by increasing their use while use among whites levelled. In contrast, blacks started out with half the annual prevalence rate of the other two groups and did *not* show any increase over the next fifteen years, leaving their more recent usage rates at nearly one-third that of whites.
- With regard to *LSD* and *hallucinogens* in general, blacks have consistently had far lower rates than whites or Hispanics, and whites have consistently had the highest rates. Both whites and Hispanics have shown a consistent increase in LSD use since 1986.
- The decline in the use of *stimulants*, which began in 1982, was greatest among whites and least among blacks. This is because

²⁵A recent article looking at a larger set of ethnic groups used groupings of respondents from adjacent 5-year intervals to get more reliable estimates of trends. See Bachman, J.G., Wallace, J.M. Jr., O'Malley, P.M., Johnston, L.D., Kurth, C.L., & Neighbors, H.W. (1991). Racial/ethnic differences in smoking, drinking, and illicit drug use among American high school seniors, 1976-1989. *American Journal of Public Health*, 81, 372-377.

Hispanics started out in 1982 at considerably lower levels than whites, and blacks at much lower levels. This decline has reduced the differences among these three groups, even though all three groups have shown some decline.

- There has been a convergence among these three racial/ethnic groups in their use of *sedatives, barbiturates, methaqualone, and tranquilizers* as use of all of these drugs has declined. In general, whites consistently have had the highest usage rates in senior year, and also the largest declines; blacks have had the lowest rates, and therefore the smallest absolute declines.
- *Crack* use has declined in all three groups, but in this case Hispanics have generally had the highest rates and blacks the lowest.
- Most of the remaining illicit drugs have shown parallel trends for all three groups.
- Like most of the illicit drugs, the *current daily alcohol* rates are lowest for blacks. (Data not shown.) They have hardly changed at all during the life of the study. Whites and Hispanics have daily usage rates now which are about equivalent, although whites had higher rates in the period 1977 through 1985.

There are large racial/ethnic differences in *binge drinking* (see Figure 17b) with blacks consistently having a rate below 20% (and now below 15%). In comparison, the rates for whites rose to a peak of around 45% in the early 1980s before declining to just over 30% a decade later. Hispanics have been in the middle, and also had a gradual decline in use during the 1980s. Hispanics have shown a slight upturn in the early 1990s.

- *Cigarette smoking* shows differential trends that are quite interesting. All three groups had daily smoking rates that were not dramatically different in the late 1970s (Figure 17b). All three groups showed declines between 1977 and 1981, with the declines somewhat stronger for blacks and Hispanics, leaving whites with the highest smoking rates in 1981. Since then, blacks have shown a consistent and continuing decline, and now have a rate of daily smoking that is only about one-fifth that of whites, whose smoking rates changed hardly at all between 1981 and 1992. The 1993 rate of daily smoking for Hispanics is down only slightly since 1981; thus, Hispanics, who previously had slightly lower rates than blacks, now have somewhat higher rates. Whites are the only group whose daily smoking rates increased in 1993.

Chapter 6

USE AT EARLIER GRADE LEVELS

Knowing the age at which young people first begin to use various drugs is important, in part because it provides a guide to the timing and nature of interventions in the school, the home, and the larger society. Any such intervention is likely to be considerably less effective in preventing drug use if it is administered after the ages of peak initiation. It also may be less effective if it substantially precedes this decision-making period. Not all drugs are begun at the same age; rather, a certain progression tends to occur, beginning with the drugs which are seen as least risky, deviant, or illegal, and progressing toward those that are more so.

Age of initiation has been ascertained from seniors by a set of questions which have been included in the study since its inception in 1975. The results have been used in this series of monographs to give a retrospective view of trends in lifetime prevalence at earlier grade levels. Because of the long time period these trends span, we continue to include here the series of figures based on seniors' responses, even though we now measure drug usage rates directly from eighth and tenth graders.

One would not necessarily expect today's eighth, tenth, and twelfth graders to give the same retrospective prevalence rate for a drug (say by sixth grade), since there are a number of differences among them. These differences can be summarized as follows:

- (1) The lower grades contain the eventual school dropouts, while twelfth grade does not. The lower grades also have lower absentee rates. For any given year both factors should cause the prevalence rates derived directly from eighth graders to be higher than the retrospective prevalence rates for eighth grade derived from tenth graders (two years later) or twelfth graders (four years later).
- (2) Each class cohort was in eighth grade in a different year, so any broad secular or historical trend in the use of a drug could contribute to differences in their reports of eighth grade experiences.
- (3) The eighth, tenth, and twelfth graders are in three different class cohorts, so any lasting differences among cohorts could contribute to a difference at any grade level, including eighth grade.

There are also two types of method artifacts which could explain observed differences in the retrospective reports of use by eighth, tenth, and twelfth graders:

- (4) Memory errors are more likely for the older respondents. They may forget that an event occurred (but this is unlikely for use of drugs), or they may not accurately remember when an event occurred. For example, an event may be remembered as having occurred more recently than it actually did.

- (5) The definition of the eligible event may change as a respondent gets older. Thus, an older student may be less likely to include an occasion of taking a sip from someone's beer as an occasion of alcohol use, or an older student may be more likely to exclude (appropriately) an over-the-counter stimulant when reporting amphetamine use. While we attempt to ask the questions as clearly as possible, some of these drug definitions are fairly subtle, and may be more difficult for the younger respondents.

INCIDENCE OF USE BY GRADE LEVEL

Tables 18a through 18c give the retrospective initiation as reported by eighth, tenth, and twelfth graders, respectively. Obviously, the older students have a longer age span over which they can report initiation. Table 18d puts together the retrospective initiation rates from all three sets of respondents in order to facilitate a comparison of reported initiation rates by particular grades.

- Eighth, tenth, and twelfth grade students all report very low usage rates (below 1%) by the end of sixth grade for *hallucinogens*, *LSD*, and *heroin*. Fewer than 2% reported any use of *cocaine* or *tranquilizers* and 4% or less reported any use of *stimulants*. *Marijuana* was tried by no more than 4.1% of youngsters by the end of sixth grade. These findings are consistent with what we have been reporting in the past based on the retrospective data from twelfth graders, and gives us much greater confidence in those retrospective reports.
- Of the illicit drugs, only *inhalants* show very large differences by age of reporting. While only 2.2% of the twelfth graders report having used inhalants by the end of sixth grade, a much higher 11.0% of the eighth graders report such use by sixth grade. Although any of the explanations offered above might explain these differences, we believe that early inhalant use may be associated with dropping out, and also that the use of the types of inhalants generally used at younger ages (glues, aerosols, butane) has been on the rise (i.e., that there has been a secular trend in use).
- *Alcohol* use by the end of sixth grade is retrospectively reported by 37% of the 1993 eighth graders, but by only 11% of the 1993 twelfth graders. Several factors probably contribute to the difference. One is a secular trend in which initiation of alcohol use appears to be occurring earlier (see Figure 18s). A second is that eventual dropouts are probably much more likely than average to drink at an early age. Still another is related to the issue of what is meant by "first use." The questions for all grades refer specifically to the first use of "an alcoholic beverage—more than just a few sips," but it is likely that the older students (twelfth graders) are more inclined to report only use that is not adult-approved, and not to count having two or three sips with

parents or for religious purposes. Younger students (eighth graders) are less likely to have had a full drink or more, and may be more likely to report first use of a limited amount. Thus, the eighth grade data probably exaggerate considerably the phenomenon of having more than a few sips, whereas the twelfth grade data do not. Note that the data from the three groups of respondents tend to converge as we ask about lifetime alcohol use by the time they reach higher grade levels.

- A fair number from all three grade levels indicate having ***gotten drunk*** by the end of sixth grade (between 3% and 9%), and much of the difference may be attributable to the differential inclusion of eventual dropouts.
- Even larger proportions indicate having had their first ***cigarette*** by the end of sixth grade (from 18% to 29%). Again, because educational attainment is very highly correlated with smoking, the differential inclusion of eventual dropouts could account for most of the difference.
- Clearly the legal drugs are the most likely to be initiated at an early age, with ***inhalants*** and ***marijuana*** likely to come next.
- Judging by the data from eighth graders (Table 18a), the peak ages for initiation of ***cigarette*** smoking appear to be in the sixth and seventh grades (22%), but with a considerable number initiating smoking even earlier. In fact, 18% of the 1993 eighth grade respondents reported having their first cigarette by fifth grade. ***Daily smoking*** appears to develop primarily in grades eight through eleven.
- ***Smokeless tobacco*** use also tends to be initiated quite early, as Tables 18a, 18b, and 18c illustrate.
- For ***alcohol***, we are more inclined to rely on the data from seniors, which suggest that the peak ages of initiation are in seventh through ninth grade. The first occasion of ***drunkenness*** is most likely to occur in grades 7 through 10. Still according to the 1993 eighth graders, some 9% of them reported having been drunk by the end of sixth grade.
- ***Inhalant*** use tends to occur early, with peak initiation rates in grades 6 through 9. Among eighth graders in 1993, some 7% had already tried inhalants prior to sixth grade.
- For ***marijuana*** the highest initiation rates are seen in grades 9 through 11, though by eighth grade 13% of the 1993 eighth graders reported having already tried marijuana.
- The illicit drugs other than marijuana and inhalants do not reach peak initiation rates until the high school years (grades 10 through 12), consistent with the progression model noted earlier.

- For most illicit drugs, half to two-thirds of those who use by twelfth grade initiate use prior to grade 10; this is true for *barbiturates* (51%), *inhalants* (58%), *PCP* (52%), *methaqualone* (63%), and *nitrites* (64%). The other illicit drugs have somewhat late initiation rates, with less than one-half of those who use by twelfth grade reporting use prior to grade 10: these include *heroin* (45%), *marijuana* (45%), *amphetamines* (42%), *tranquilizers* (44%), *opiates other than heroin* (47%), *cocaine* (36%), *crack* (38%), *steroids* (30%), and *LSD* (29%).

TRENDS IN USE AT EARLIER GRADE LEVELS

Using the retrospective data provided by members of each senior class concerning their grade at first use, it has been possible to reconstruct lifetime prevalence trend curves for lower grade levels over many earlier years. Obviously, data from school dropouts are not included in any of the curves. Figures 18a through 18x show the reconstructed lifetime prevalence curves for earlier grade levels for a number of drugs.

- Figure 18a provides the trends at each grade level for lifetime use of *any illicit drug*. It shows that for all grade levels there was a continuous increase in illicit drug involvement through the 1970s. The increase fortunately was quite small for use prior to seventh grade; only 1.1% of the class of 1975 reported having used an illicit drug in sixth grade or below (which was in 1969 for that class), but the figure has increased modestly, and for the graduating class of 1993 is 3.2% (which was in 1987 for that class). The lines for the other grade levels all show much steeper upward slopes. For example, about 37% of the class of 1975 had used some illicit drug by the end of grade 10, compared to 52% of the class of 1982. This statistic has now fallen back to 28% for the class of 1993.
- Beginning in 1980 there was a leveling off at the high school level (grades 10, 11, and 12) in the proportion becoming involved in illicit drugs. The leveling in the lower grades came about a year earlier.
- Most of the increase in any illicit drug use was due to increasing proportions using marijuana. We know this from the results in Figure 18b showing trends for each grade level in the proportion having used *any illicit drug other than marijuana* in their lifetime. Compared to Figure 18d for marijuana use, these trend lines are relatively flat throughout the 1970s and, if anything, began to taper off among ninth and tenth graders between 1975 and 1977. The biggest cause of the increases in these curves from 1978 to 1981 was the rise in reports of amphetamine use. As noted earlier, we suspect that at least some of this rise was artifactual. If amphetamine use is removed from the calculations, even greater stability is shown in the proportion using

illicit drugs other than marijuana or amphetamines. (See Figure 18c.)

- As can be seen in Figure 18d, for the years covered across the decade of the 1970s, *marijuana* use had been rising steadily at all grade levels down through the seventh and eighth grades. Beginning in 1980, lifetime prevalence for marijuana began to decline for grades 9 through 12. Declines in grades 7-8 began a year later, in 1981.

There was also some small increase in marijuana use during the 1970s at the elementary level, prior to seventh grade. Use by sixth grade or lower rose gradually from 0.6% for the class of 1975 (who were sixth graders in 1968-69) to a peak of 4.3% in the class of 1984 (who were sixth graders in 1977-78). Use began dropping thereafter and for the class of 1993 is down to 2.3%. (The more up-to-date data from the 1993 eighth graders, which are not exactly comparable because of the inclusion of eventual dropouts, yield a prevalence estimate of 4.1% for these students when they were sixth graders in 1991.)

- Questions about age at first use for *inhalants* (unadjusted for the nitrites) were introduced in 1978. The retrospective trend curves (Figure 18e) suggest that during the mid-1970s, experience with inhalants decreased slightly for most grade levels and then began to rise. For the upper grade levels there was a continued rise, peaking with the classes of 1989 and 1990. The class of 1992 showed lower rates of initiation than its two predecessor classes at all grade levels, but the class of 1993 showed a resumption of the upward trends.
- Since grade-at-first-use data have been gathered for the *nitrites* beginning in 1979, only limited retrospective data exist (Figure 18f). These do not show the recent increase observed for the overall inhalant category. To the contrary, they show a substantial decline. Because their use level has gotten so low, their omission by some respondents from their reports of overall inhalant use has much less effect on the inhalant statistics in recent years than it did when nitrite use was more common.
- Lifetime prevalence of *hallucinogen* use (unadjusted for underreporting of PCP) began declining among students at most grade levels in the mid-1970s (Figure 18g), and this gradual decline continued through the mid-1980s, reaching low points at several grade levels for the class of 1986. Recent classes have shown some fluctuations, with an increase in initiation among tenth graders in 1992 and twelfth graders in 1993.
- Trend curves for the specific hallucinogen, *LSD* (Figure 18h), are similar in shape (though at lower rates, of course). Incidence rates for *psychedelics other than LSD* (data not presented) have shown some

decreases in incidence rates in recent classes, resulting in little net change between the classes of 1986 and 1993 in overall hallucinogen incidence rates.

- There is less trend data for **PCP**, since questions about grade of first use for this drug were added in 1979. However, some interesting results emerge. A sharp downturn began around 1979 (see Figure 18i), and use declined in all grade levels until 1987; since then there has been little change.
- **Cocaine** use at earlier grade levels is given in Figure 18j. One clear contrast to the marijuana pattern is that more than half of initiation into cocaine use takes place in grades 10 through 12 (rather than earlier, as has been the case for marijuana in most years). Further, most of the increase in cocaine experience between 1976 and 1980 occurred in grades 11 and 12, not below. After 1980, experience with cocaine generally remained fairly level until after 1986, when use among eleventh and twelfth graders began to show a significant decline. (There seemed to be little or no decline in the lower grades.)
- Questions on age of first use for **crack** were first asked of the class of 1987. The retrospective data show crack initiation falling at all grade levels but the largest proportional declines occurred in the last few years for grades 11 and 12 (see Figure 18k). However, **powder cocaine** clearly fell more sharply than crack (see Figure 18l), again mostly in the upper grade levels.
- Though difficult to see in Figure 18m, the **heroin** lifetime prevalence figures for grades 9 through 12 all began declining in the mid-1970s, then leveled, and show no evidence of reversal yet.
- The lifetime prevalence of use of **opiates other than heroin** has remained relatively flat at all grade levels since the mid-1970s, with the class of 1991 showing the first evidence of decline when they reached the upper grades (Figure 18n). Since then, the rates have leveled again and may have even risen a bit in the lower grades.
- The lifetime prevalence statistics for **stimulants** peaked briefly for grade levels 9 through 12 during the mid-1970s (see Figure 18o). However, they showed a sharp rise in the late 1970s at virtually all grade levels. As has been stated repeatedly, we believe that some, perhaps most, of this upturn was artifactual in the sense that nonprescription stimulants accounted for much of it. However, regardless of what accounted for it, there was a clear upward secular trend, that is, one observed across all cohorts and grade levels—beginning in 1979. The unadjusted data from the class of 1983 gives the first indication of a reversal of this trend. The adjusted data from the classes of 1982 through 1993 suggest that the use of

stimulants leveled around 1982 and has fallen appreciably since in grades 9 through 12. There is less evidence of a decline in lifetime prevalence among seventh and eighth graders.

- As the graphs for the two subclasses of sedatives—barbiturates and methaqualone—show, the trend lines have been quite different for them at earlier grade levels as well as in twelfth grade (see Figures 18p and 18q). Since about 1974 or 1975, lifetime prevalence of *barbiturate* use had fallen off sharply for the upper grade levels for all classes until the late 1970s; the lower grades showed some increase in the late 1970s (perhaps reflecting the advent of some look-alike drugs) and in the mid-1980s, all grades resumed the decline. Most recently there is some leveling in the rates.

During the mid-1970s *methaqualone* use started to fall off at about the same time as barbiturate use in nearly all grade levels, but dropped rather little and then flattened. Between 1978 and 1981 there was a fair resurgence in use in all grade levels; but after 1982 there was a sharp decline to near zero.

- Lifetime prevalence of *tranquilizer* use (Figure 18r) also began to decline at all grade levels in the mid-1970s. It is noteworthy that, like sedatives, the overall decline in tranquilizer use has been considerably greater in the upper grade levels than the lower ones. Overall, it would appear that the tranquilizer trend lines have been following a similar course to those of barbiturates. So far, the curves are different only in that tranquilizer use continued a steady decline among eleventh and twelfth graders since 1977 (at least through the class of 1990), while barbiturate use had its decline interrupted for awhile in the early 1980s.
- The curves for lifetime prevalence of *alcohol* at grades 11 and 12 (Figure 18s) are very flat between the early 1970s and late 1980s, reflecting little change over more than a decade. More recent classes (1989-1993) show slight declines. At the seventh through tenth grade levels, the curves show slight upward slopes in the early 1970s, indicating that, compared to the earlier cohorts (prior to the class of 1978), more recent classes initiated use at earlier ages. There was an even sharper upward trending in the mid-1980s, particularly at the seventh through eighth grade level. Thus, while 27% of the class of 1975 first used alcohol in eighth grade or earlier, 36% in the class of 1993 had done so. Females account for most of the change; 42% of females in the class of 1975 first used alcohol prior to tenth grade, compared to 53% in the class of 1993.

Beginning with the class of 1986, we added questions asking seniors when did they first "drink enough to feel drunk or very high". Figure 18t shows fairly similar curves to those for lifetime prevalence of

having been *drunk*. The most recent classes (1991-1993) have shown modest declines in this behavior at all grade levels above grade six.

- Beginning with the class of 1986, we added questions asking seniors "when did you smoke your first cigarette." Figure 18u shows that initiation rates were quite high by grade 6 (which was in 1980) for the class of 1986 (over 20%), and have fallen only slightly in subsequent classes (18% for the class of 1993, who were in grade 6 in 1987).

Substantial additional initiation occurs in grades 7 and 8: over 40% of the class of 1986 had smoked a cigarette by grade 8, and this figure stands at 39% for the class of 1993. Initiation has declined very slightly for all grade levels in recent classes, until the class of 1993 which showed an increase.

- Figure 18v presents the smoking measure contained in the study since its inception: lifetime prevalence of cigarette smoking on a daily basis. It shows that initiation to *daily smoking* was beginning to peak at the lower grade levels in the early to mid-1970s. This peaking did not become apparent among high school seniors until some years later. In essence, these changes reflect in large part cohort effects—changes which show up consistently across the age band for certain class cohorts. Because of the highly addictive nature of smoking, this is a type of drug-using behavior in which one would expect to observe enduring differences between cohorts if any are observed at a formative age. The classes of 1982 and 1983 showed some leveling of the previous decline, but the classes of 1984 through 1986 showed an encouraging resumption of the decline while they were in earlier grade levels. The data from the classes of 1987 and 1988 showed a pause in the decline; but the classes of 1989, 1990, and 1991 have unfortunately shown a new *rise* in the lifetime prevalence of daily cigarette use as they passed through all grade levels. This rise is first discernible when these class cohorts were in eighth grade (between 1984 and 1987). The class of 1993 continued this rise after a brief pause in 1992.

- *Smokeless tobacco* use (Figure 18w) was first asked of the class of 1986. Like cigarettes, it too showed a cohort-linked pattern of change. Since the class of 1986 there was a rise and then a decline in use in all grades, with the class of 1990 showing peak levels of use at most grades. (In the upper grades, there was some decline preceding the peak class of 1990.) Since the class of 1990 there has been some decline at all grade levels.

- *Steroid* use was first asked of the class of 1989. The classes of 1989 through 1991 showed about a one-third drop in rates at grade 9 and each higher grade (Figure 18x). Rates of initiation at all grade levels have stabilized in 1992 and 1993.

Chapter 7

DEGREE AND DURATION OF DRUG HIGHS

While it is possible to ask questions about use in terms of standard quantity measures for substances which are manufactured and sold legally (e.g., alcohol and cigarettes) most of the illicitly-used drugs are not purchased in precisely defined (or known) quantities or purities. Therefore, in order to secure indirect measures of the dose or quantity of a drug consumed per occasion, and also to help characterize the typical drug-using event for each type of drug, we have asked twelfth grade respondents on one of the six questionnaire forms to indicate—for each drug that they report having used in the past twelve months—how high they usually get, and how long they usually stay high. The results from those questions are discussed in this chapter, along with trends since 1975, in the degree and duration of the highs usually associated with each of the relevant drugs. Since these questions were not included in the questionnaires administered to eighth and tenth graders, all of the data presented in this chapter are derived from high school seniors.

DEGREE AND DURATION OF HIGHS AMONG TWELFTH GRADERS

Figure 19 shows the proportion of 1993 seniors who say that they *usually* get "not at all" high, "a little" high, "moderately" high, or "very" high when they use a given type of drug. The percentages are based on all respondents who report use of the given drug class in the previous twelve months, and therefore each bar cumulates to 100%. The ordering from left to right is based on the percentage of users of each drug who report that they usually get "very" high.

- **Hallucinogens** (LSD and hallucinogens other than LSD) and **heroin** usually produce intense highs. Beginning in 1982, this question was omitted for heroin because of the small numbers of cases available each year. An averaging across earlier years indicated that it would rank very close to LSD.
- Following closely are **cocaine** and **marijuana** with two-thirds of the users of each saying they usually get moderately high or very high when using the drug. Methaqualone and barbiturates are no longer included in these item sets. (Methaqualone used to rank quite high on the question about the intensity of the highs attained.)
- Three of the major psychotherapeutic drug classes—**opiates other than heroin**, **stimulants**, and **tranquilizers**—are used less often to get high; but substantial proportions of users (from 22% for tranquilizers to 44% for other opiates) say they usually get moderately or very high after taking these drugs.
- Relatively few of the many seniors using **alcohol** say that they usually get *very* high when drinking, although nearly half usually get at least

FIGURE 19

Degree of Drug Highs Attained by Recent Users
Twelfth Graders, 1993

NOTE: Data are based on answers from respondents reporting any use of the drug in the prior twelve months. Heroin is not included in this figure because these particular questions are not asked of the small number of heroin users.

moderately high. For a given individual we would expect more variability in the degree of intoxication achieved with alcohol from occasion to occasion than with most other drugs. Therefore, many drinkers probably get very high at least sometimes, even if that is not "usually" the case, which is what the question asks.

- Figure 20 presents the data on the duration of the highs usually obtained by users of each class of drugs. The drugs are arranged in the same order as for intensity of highs to permit an examination of the amount of correspondence between the degree and duration of highs.
- As can be seen in Figure 20, those drugs which result in the most intense highs generally tend to result in the longest highs. For example, *LSD* and *hallucinogens other than LSD* rank one and two respectively on both dimensions, with substantial proportions of the users of these drugs (65% and 38%, respectively) say they usually stay high for seven hours or more.
- There is not a perfect correspondence between degree and duration of highs. Although the highs obtained with *marijuana* tend to be relatively high in degree, they are shorter in duration in comparison with many other drugs. About half of users (49%) usually stay high one to two hours, and the modal duration is one to two hours. Still, over one-third of the users (37%) report usually staying high three to six hours, and another 4% stay high for seven hours or more.
- Among *cocaine* users, 43% stay high one to two hours, and 24% stay high three to six hours. More than one in four (16%) stay high seven or more hours. The remaining 17% say they usually don't get high.
- Among those who get high, the modal duration of highs for users of *marijuana*, *cocaine*, and *stimulants* is one to two hours.
- In sum, drugs vary considerably in both the duration and degree of the highs usually obtained with them, though many have a modal duration of one to two hours. Sizeable proportions of the users of all of these drugs report that they usually get high for at least three hours per occasion. For a number of drugs—particularly the hallucinogens, but also opiates other than heroin and cocaine—appreciable proportions usually stay high for seven hours or more. (These data obviously do not address the qualitative differences in the experiences of being "high.")

TRENDS IN DEGREE AND DURATION OF DRUG HIGHS

There have been several important shifts over the years in the degree or duration of highs usually experienced by users of the various drugs. Recall that only fairly recent users, who used in the prior twelve months, answer these questions.

FIGURE 20

**Duration of Drug Highs Attained by Recent Users
Twelfth Graders, 1993**

NOTE: Data are based on answers from respondents reporting any use of the drug in the prior twelve months. Heroin is not included in this figure because these particular questions are not asked of the small number of heroin users.

- The *degree* of high obtained from *cocaine* appears to have remained fairly constant over the past nineteen years. The story on the *duration* of highs, however, has been more complex. At the onset phase of the cocaine epidemic (1976-1979), there was a shortening of the average duration of highs; the proportion of users reporting highs of two hours or less rose from 30% to 49%. The proportion reporting these short highs continued to rise to 64% by the late 1980's and then fell to 60% in 1993. Put another way, in the decline phase of the epidemic the *average duration* of cocaine highs has increased; in 1989, 36% reported highs lasting three hours or more, compared to 52% in 1992 and 40% in 1993.
- For *opiates other than heroin*, between 1975 and 1993 there has been a general decline in both the intensity of the highs usually experienced *and* in the duration of those highs. In 1975, 39% said they usually got "very high" vs. 16% in 1993. The proportion usually staying high for seven or more hours dropped from 28% in 1975 to 16% in 1993. This shift has occurred, in part, due to a substantial increase in the proportion of users who say they do not take these drugs "to get high" (4% in 1975 vs. 25% in 1993). Because the actual prevalence of opiate use has dropped only modestly, this would suggest that increasing use for self-medication may have masked, to some degree, a decrease in recreational use.
- Between 1975 and 1981, a period of increase in *stimulant* use among seniors, there was a decrease in the average *degree* of high obtained, much as occurred with cocaine. The proportion of recent users usually getting very high or moderately high fell from 60% in 1975 to 37% in 1981. Consistent with this, the proportion of users saying they simply "don't take them to get high" increased from 9% in 1975 to 20% by 1981. (This statistic rose to 25% in 1991, before dropping to 19% in 1993, a year of increased use of stimulants.)

Also, the average reported *duration* of stimulant highs was declining over the longer term; 41% of the 1975 users said they usually stayed high seven or more hours vs. only 17% of the 1981 users.²⁶ (Though there were many fewer users by 1993, 10% of them said they usually stay high that long.)

These substantial decreases in both the degree and duration of highs strongly suggest that, over the life of the study, there has been some shift in the purposes for which stimulants were being used. An examination of data on self-reported reasons for use tends to confirm

²⁶In 1982, the questionnaire form containing the questions on degree and duration of highs clarified the amphetamine questions to eliminate the inappropriate inclusion of nonprescription stimulants. One might have expected this change to have increased the degree and duration of highs reported, given that real amphetamines would be expected to have greater psychological impact on the average; but the trends still continued downward that year.

this conclusion. In essence, between 1979 and 1984, there was a relative decline in the frequency with which recent users mention "social/ recreational" reasons for use, and between 1976 and 1984 there was an increase in mentions of use for instrumental purposes.²⁷ Since 1984 the shifts have been slight and tend *not* to be continuing the pre-1984 trends.

- With respect to the social/recreational shifts from 1979 to 1984, the percent of all recent users citing "to feel good or get high" as a reason for stimulant use declined from 58% to 45%; in 1993 the figure was 46%. Similarly, "to have a good time with my friends" declined from 38% to 30% between 1979 and 1984; in 1992 it was 31%, but in 1993 it rose to 36%. There were shifts toward more instrumental use between 1976 and 1984: "to lose weight" increased by 15% (to 41%); "to get more energy" increased 13% (to 69%); "to stay awake" increased by 10% (to 62%) and "to get through the day" increased by 9% (to 32%). Since 1988, these instrumental objectives have been mentioned somewhat less often by users: In 1993, "to lose weight" is mentioned by 36% of recent users; "to get more energy" by 54%; "to stay awake" by 46%; and "to get through the day" by 21%. However, the proportions indicating recreational motives have changed relatively little since 1984.
- Despite the earlier *relative* decline in recreational reasons for use of stimulants, it also appears that there was at least some increase in the *absolute* level of recreational use, though clearly not as steep an increase as the trends through 1981 in overall use might have suggested. The data on the percent of seniors exposed to people using amphetamines "to get high or for kicks," which will be discussed further in Chapter 9, showed a definite increase between 1976 and 1981. There was no further increase in exposure to people using for those purposes in 1982, however, suggesting that recreational use, as well as overall use, had leveled off; since 1982 there has been a considerable decrease in such exposure (from 50% to 25% of all seniors), indicating a substantial drop in the total number of people using stimulants for recreational purposes.
- The degree and duration of highs achieved by *tranquilizer* users have been decreasing generally since about 1980. While only 30% of the 1975 senior users said they did not usually get high, 50% of the 1993 users said that they did not.
- For *marijuana* there had been some general downward trending between 1978 and 1983 in the degree of the highs usually obtained. In 1978, 73% of users said they usually got "moderately high" or "very

²⁷Johnston, L.D. & O'Malley, P.M. (1986). Why do the nation's students use drugs and alcohol? Self-reported reasons from nine national surveys. *Journal of Drug Issues*, 16, 29-66.

high"—a figure which dropped to 64% by 1983. In 1993, a year of increased use, this proportion rose back to 72% (from 66% in 1992). Some interesting changes also took place in the duration figures between 1978 and 1983. Recall that most marijuana users say they usually stay high either one to two hours or three to six hours. Between 1975 and 1983 there was a steady decline in the proportion of users saying they stayed high three or more hours (from 52% in 1975 to 35% in 1983); the proportion stands at 40% in 1993. Until 1979, this shift could have been due almost entirely to the fact that progressively more seniors were using marijuana; and the users in later classes, who might *not* have been users if they were in earlier classes, probably tended to be relatively light users. We deduce this from the fact that the percentage of *all* seniors reporting three to six hour highs remained relatively unchanged from 1975 to 1979; while the percentage of all seniors reporting only one to two hour highs increased steadily—from 16% in 1975 to 25% in 1979.

- After 1979, the overall prevalence rate declined substantially, but the shift toward shorter average highs continued through 1983. Thus we must attribute this shift to another factor, and the one which seems most likely is a general shift, even among the most marijuana-prone segment, toward a less frequent (or less intense) use of the drug. The drop in daily prevalence since 1979, which was disproportionate to the drop in overall prevalence, is consistent with this interpretation. Also consistent is the fact that the average number of "joints" smoked per day (among those who reported any use in the prior month) had been dropping. In 1976, 49% of the recent (past 30-days) users of marijuana indicated that they averaged less than one joint per day in the prior 30 days, but by 1993 this proportion had risen to 64%. In sum, not only are fewer high school students now using marijuana than in the early years of this study, but those who are using seem to be using less frequently and to be taking smaller amounts (and doses of the active ingredient) per occasion, at least through 1988. More recently, on the other hand, there has been some slight upward trend in average duration of highs: in 1993, 40% of users reported usually staying high for three or more hours, compared to 34% in 1988.
- This is of particular interest in light of the evidence from other sources that the THC content of marijuana has risen dramatically since the late 1970s. The evidence here would suggest that users have titrated their intake to achieve a certain (perhaps declining) level of high, and thus are smoking less marijuana as measured by volume.
- There are no clearly discernible long-term patterns in the intensity or duration of the highs being experienced by users of *LSD* or *hallucinogens other than LSD*. Although the proportion of LSD users who say they usually get "very high" has fallen some since 1989 (from 71% to 57% in 1993). The proportion of users of hallucinogens

Monitoring the Future

other than LSD who report getting "very high" has also dropped, from 57% in 1989 to 44% in 1993.

- Data are not collected for highs experienced in the use of *inhalants*, the specific *nitrites*, *PCP*, or *heroin*.
- The intensity and duration of highs associated with *alcohol* use generally have been stable throughout the study period, although there are indications of a slight increase in the percentage of alcohol users who do not usually get high; in 1993, 24% of users say they usually get "not at all high," compared to 20% in 1988.

Chapter 8

ATTITUDES AND BELIEFS ABOUT DRUGS

When this study was launched in 1975, we allocated a considerable amount of questionnaire content to the measurement of certain attitudes and beliefs related to drug use—ones which we believed might prove important in explaining young people's use of drugs. In the intervening years, this has proven to be a particularly fruitful investment.

In this section we present the cross-time results for three of these sets of attitude and belief questions. One set concerns students' beliefs about how harmful the various kinds of drug use are for the user; the second concerns the degree to which students personally disapprove of various kinds of drug use; and the third, asked only of seniors, deals with their attitudes about various forms of legal prohibition. Chapter 9 will present results on the closely related topics of parents' and friends' attitudes about drugs, as students perceive them.

As the data below show, overall percentages of students disapproving various drugs, and the percentages believing their use to involve serious risk tend to parallel the percentages of actual users. For example, of the illicit drugs, marijuana is the most frequently used and one of the least likely to be seen as risky to use. This and many other such parallels suggest that the individuals who disapprove use of a drug or to view its use as involving risk are less likely to use it. A series of individual-level analyses of these data confirms this conclusion: strong correlations exist between individual use of drugs and the various attitudes and beliefs about those drugs. Those seniors who use a given drug also are less likely to disapprove its use or to see it as dangerous; also, they are more likely to report their own parents and friends as being at least somewhat more accepting of its use.

Many of the attitudes and beliefs about drug use reported below changed dramatically during the life of the study, along with actual drug-using behaviors. Beginning in 1979, scientists, policy makers, and in particular the electronic and printed media, gave considerable attention to the increasing levels of regular marijuana use among young people, and to the potential hazards associated with such use. As will be seen below, after 1979 attitudes and beliefs about regular use of marijuana shifted in a more conservative direction—a shift which coincides with a reversal in the previous rapid rise of daily use, and which very likely reflects the impact of this increased public attention. Between 1986 and 1987, a similar and even more dramatic shift began to occur for cocaine and continued for some years. In the last two years, however, there has been some turnaround in these attitudes, accompanied by an increase in the use of certain drugs (e.g., marijuana, LSD, amphetamines) and perhaps presaging an increase in the use of others (e.g., cocaine).

PERCEIVED HARMFULNESS OF DRUGS

Beliefs about Harmfulness Among Twelfth Graders

- A substantial majority of high school seniors perceive regular use of *any of the illicit drugs* as entailing "great risk" of harm for the user.

TABLE 19

Monitoring the Future

As Table 20 shows, almost 90% of the seniors feel this way about regular use of *crack*, *cocaine powder*, and *heroin*. The proportions attributing great risk to regular use of *LSD*, *amphetamines*, and *barbiturates* are 79%, 70%, and 66%, respectively.

- Regular use of *cigarettes* (i.e., one or more packs a day) is judged by about two-thirds of all seniors (70%) as entailing a great risk of harm for the user.
- Regular use of *marijuana* is judged to involve great risk by 73% of the seniors. This number is a higher proportion than those who judge cigarette smoking to involve great risk, perhaps in part because marijuana can have dramatic short-term impacts on mood, behavior, memory, etc. (in addition to any long-term physiological impacts) points which have been stressed in recent years in the advertising campaign of the National Partnership for a Drug-Free America.
- Regular use of *alcohol* is more explicitly defined in several questions providing greater specificity on the amount of use. Over a quarter of seniors (28%) associate great risk of harm with having one or two drinks almost daily. Close to half (48%) think there is great risk involved in having five or more drinks once or twice each weekend. About two-thirds (68%) think the user takes a great risk in consuming four or five drinks nearly every day. It is notable that about one-third do not view even this pattern of regular heavy drinking as entailing great risk.
- Very few seniors (8%) believe there is much risk involved in trying an *alcoholic beverage* once or twice.
- Compared with perceptions about the risks of regular use of each drug, many fewer respondents feel that a person runs a "great risk" of harm by simply trying the drug once or twice.
- Still, experimental use of most illicit drugs is viewed as risky by substantial proportions of high school seniors. The percentages associating great risk with experimental use rank order as follows: 58% for *crack*, 53% for *cocaine powder*, 51% for *PCP*, 51% for *heroin*, 40% for *LSD*, 31% for *amphetamines*, 29% for *barbiturates*, and 22% for *marijuana*.
- The use of *crack* and *cocaine powder* at experimental and occasional levels of use engenders about the same level of perceived risk at the regular use level.

Beliefs about Harmfulness Among Eighth and Tenth Graders

An abbreviated set of the same questions on harmfulness was asked of eighth and tenth graders beginning in 1991, and additional questions were added about the perceived harmfulness of inhalants and smokeless tobacco (see Table 19). Although the findings are quite similar to those for seniors in general, there are some interesting differences, as well.

- The most important difference is observed for **regular cigarette smoking**. It is an unfortunate fact that perceived risk is lowest at the ages where initiation is most likely to occur. While nearly 70% of seniors see great risk in pack-a-day smoking, only about 60% of the tenth graders and about 50% of the eighth graders do.
- Regular use of **smokeless tobacco** is viewed as entailing great risk by slightly more than one-third (37%) of eighth grade students, and by only 44% of tenth graders. Again, because this behavior is often initiated at early ages, these figures are disturbingly low.
- In contrast to tobacco use, the younger students are somewhat more likely to see **marijuana** use as dangerous than are seniors. The same is true for the regular use of **crack** and **cocaine powder**.
- Eighth and tenth grade students are more likely to see weekend **binge drinking** as dangerous, though their views on daily drinking and experimentation are not much different from seniors.
- These various differences among grade levels could reflect maturational (age) effects, or cohort effects, perhaps due to younger cohorts getting more drug education, or some combination of these effects. It will be a few years before we can begin to distinguish empirically among these interpretations.
- Experimentation with **inhalants** (which is only included in the eighth and tenth grade questionnaire) is seen as dangerous by relatively low proportions (37% and 41%, respectively), which may well explain the widespread use of inhalants at these ages.

TRENDS IN PERCEIVED HARMFULNESS OF DRUGS

Trends in Perceived Harmfulness Among Twelfth Graders

Several very important trends have been taking place in recent years in these beliefs about the dangers associated with using various drugs (see Table 20 and Figures 21a through 29b).

- One of the most important trends has involved **marijuana** (Figure 21a). From 1975 through 1978 there had been a decline in the harmfulness perceived to be associated with all levels of marijuana use;

FIGURE 21a

Trends in Perceived Harmfulness of Marijuana Use for Twelfth Graders

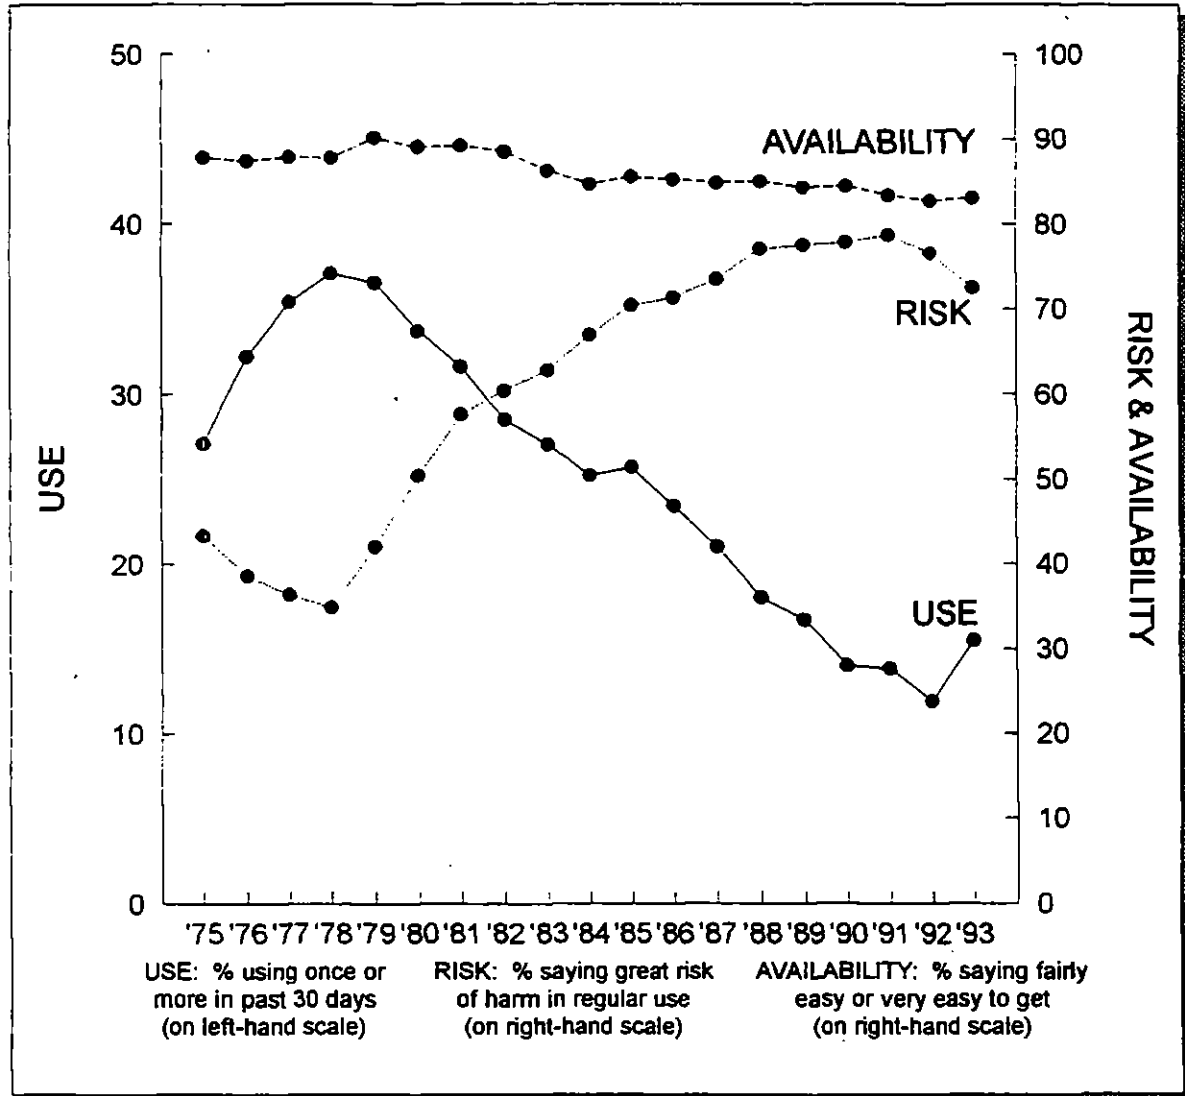

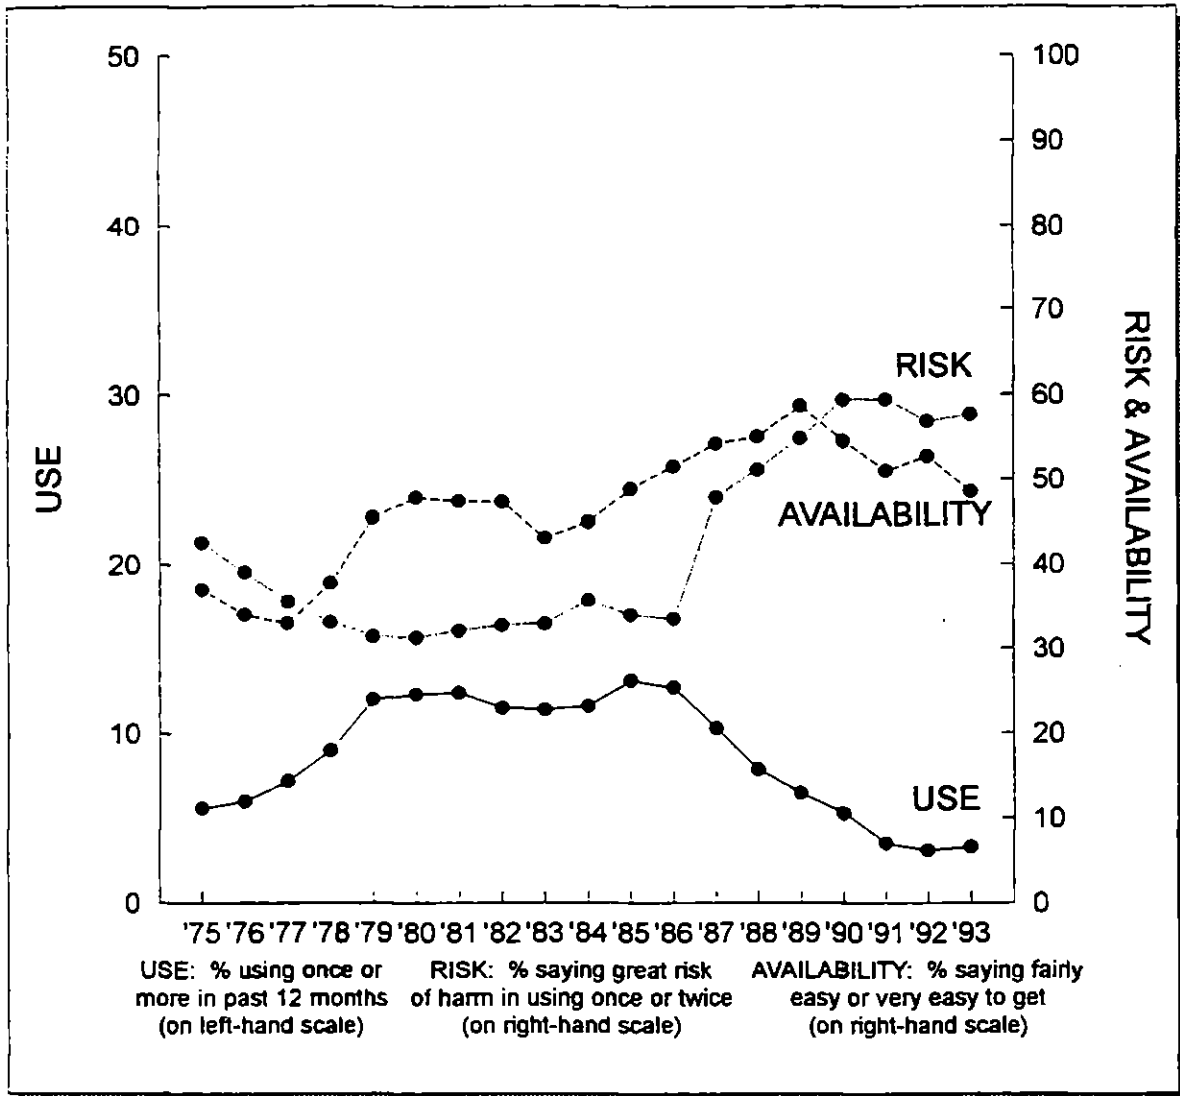

FIGURE 24

**Cocaine: Trends in Perceived Availability,
Perceived Risk of Trying, and
Prevalence of Use in Past Year for Twelfth Graders**

but in 1979, for the first time, there was an increase in these proportions. The increase preceded any appreciable downturn in use and continued fairly steadily through 1991. However, in 1992 perceived risk began to drop, and while use continued to fall that year in 1993 use rose sharply, and perceived risk dropped further. We believe these changes in beliefs about the dangers of marijuana played a critical role in causing a turnaround in use. In this case, the decrease in perceived risk preceded the change in behavior by a year.

- In earlier years, by far the most impressive increase (in absolute terms) in perceived risk occurred for **regular marijuana use**, where the proportion perceiving such use as involving a great risk doubled in just seven years, from 35% in 1978 to 70% in 1985. Subsequently, the proportion continued to increase, more slowly, reaching 79% in 1991. The dramatic change between 1978 and 1985 occurred during a period in which a substantial amount of scientific and media attention was being devoted to the potential dangers of heavy marijuana use. Young people also had ample opportunity for vicarious learning about the effects of heavy use through observation, because such use was so widespread among their peers. Increases in concerns about the harmfulness of occasional and even experimental use also occurred; these increases were even larger in proportional terms, though not in absolute terms. For example, the proportion of seniors seeing great risk in **trying marijuana** rose from 8% in 1978 to 27% in 1991, and the corresponding rise for **occasional marijuana use** was from 12% to 41%.

There are several possible explanations for the decline in perceived risk. One is that perhaps the perceived risk of marijuana use had reached an unrealistically high level of risk assessment, particularly relative to the risks posed by other drugs. Another possibility—not necessarily inconsistent with the first—is that some of the forces giving rise to the increases in perceived risk are becoming less influential. Some possibilities: (1) fewer of today's students are observing first-hand the effects of heavy marijuana use among their peers; (2) the media coverage of drugs and incidents resulting from drug use (particularly marijuana) has decreased substantially in recent years; (3) the advertising campaign of the Partnership for a Drug-Free America is reaching fewer young people or becoming less salient for young people; (4) the forces *encouraging* use have become more visible in the past couple of years, e.g., certain rock groups, and their encouragement may cause youngsters to think that it must not be so dangerous after all. Any or all of these factors could result in perceptions of risk sliding back toward earlier levels.

- Returning to the large change which already has occurred, Figure 23 shows the trend in the perceived risk of regular marijuana use and the trend in thirty-day prevalence of use to illustrate more clearly their

degree of covariance over time, which we interpret as reflecting a causal connection.²⁸ Also included is the trend line for the perceived availability of marijuana to show its lack of covariance with use, and thus its inability to explain the downturn.

We have hypothesized that perceived risk operates not only directly on use, but also indirectly through its impact on personal disapproval; and that personal disapproval in turn operates directly on use, and in the collective, indirectly by influencing peer norms. Presumably there is some lag in the indirect effects taking place. While perceived risk began to fall in 1992, personal disapproval did not begin to decline for experimental marijuana use until 1993, when it dropped sharply and use rose sharply.

- A similar cross-time profile of attitudes has been emerging for **cocaine** (Figure 22a). First, the percentage who perceived great risk in **trying cocaine** once or twice dropped steadily from 43% to 31% between 1975 and 1980, which generally corresponds to the period of rapidly increasing use. However, rather than reversing sharply, as did perceived risk for marijuana, perceived risk for experimental cocaine use moved rather little for the next six years, 1980 to 1986, corresponding to a fairly stable period in terms of actual prevalence in use. Then in 1987 perceived risk for experimenting with cocaine jumped sharply from 34% to 48% in a single year and in that year the first significant decline in use took place. From 1987 to 1989 it continued to rise as use fell. Perceived risk reached its peak around 1991, and since then has decreased very slightly. Trends in attitudes toward **crack** have been similar to those of powder cocaine.

We think these changes in beliefs had an important impact on the behavior. Perceived risk for **regular cocaine use** began to rise first, increasing gradually from 69% in 1980 to 82% in 1986; but we believe that change did not translate into a change in behavior, unlike what happened for marijuana, because so few high school seniors were regular users and most of them probably did not ever expect to be. Thus, as we had predicted earlier, it was not until seniors' attitudes about behaviors which they saw as relevant to themselves began to change (i.e., for experimental and occasional cocaine use) that these

²⁸We have addressed in a journal article an alternate hypothesis that a general shift toward a more conservative lifestyle might account for the shifts in both attitudes and behaviors. The empirical evidence tended to contradict that hypothesis. Bachman, J.G., Johnston, L.D., O'Malley, P.M., & Humphrey, R.H. (1988). Explaining the recent decline in marijuana use: Differentiating the effects of perceived risks, disapproval, and general lifestyle factors. *Journal of Health and Social Behavior*, 29 92-112. And Johnston (1982) showed that an increasing proportion of the quitters and abstainers from marijuana use were reporting concern over the physical and psychological consequences of use as reasons for their non-use. A review and analysis of recent changes in marijuana use by American young people. In *Marijuana: The national impact on education* (pp. 8-13). New York: American Council on Marijuana.

attitudes began to affect their behavior.^{29,30} Figure 24 shows trends in perceived risk, perceived availability, and actual use simultaneously—again, to show how shifts in perceived risk could explain the downturn in use while shifts in availability could not.

We attributed changes in actual drug-use behavior between 1986 and 1991 to changes in the risk associated with experimental and occasional use. We believe the changes in these attitudes resulted from two factors: (1) the greatly increased media coverage of cocaine and its dangers which occurred in that interval, including many anti-drug "spots," and (2) the widely publicized deaths in 1986 of sports stars Len Bias and Don Rogers, both of which were caused by cocaine. The latter events, we believe, helped to bring home first the notion, that no one—regardless of age or physical condition—is invulnerable to being killed by cocaine, and second the notion that one does not have to be an addict or regular user to suffer such adverse consequences. Clearly the addictive potential of cocaine was emphasized heavily in the media during that period, as well.

As with marijuana, 1991 and 1992 saw a leveling (and even a slight decline among eighth graders) in the perceived risks of *powder cocaine* and *crack*. In 1993 a decline in these beliefs was observed at all three grade levels. The same types of explanations come to mind here as those discussed above for marijuana. This could prove to be an important development if perceived risk is, as we believe, the strongest deterrent to use among young people. This significant reversal of beliefs has set the stage for a resurgence in use, particularly when one realizes that the proportions of students using two of the "gateway drugs"—cigarettes and marijuana—has risen already.

- For most of the illicit drugs other than marijuana and cocaine, the period from 1975 to 1979 revealed a modest but consistent trend in the direction of fewer students associating much risk with experimental or occasional use of them (Table 20 and Figures 25a, 26a, 27a). Only for *amphetamines* and *barbiturates* did this trend continue beyond 1979, until about 1982.

Over the next several years there was little change, although perceived risk of harm in experimental or occasional use of the illicit drugs other than marijuana all dropped slightly in 1985 and 1986. However, the

²⁹See also Bachman, J.G., Johnston, L.D., & O'Malley, P.M. (1990). Explaining the recent decline in cocaine use among young adults: Further evidence that perceived risks and disapproval lead to reduced drug use. *Journal of Health and Social Behavior*, 31, 173-184. For a discussion of perceived risk in the larger set of factors influencing trends, and for a consideration of the forces likely to influence perceived risk, see also, Johnston, L.D. (1991). Toward a theory of drug epidemics. In R.L. Donohew, H. Sypher, & W. Bukoski (Eds.) *Persuasive communication and drug abuse prevention* (pp. 93-132). Hillsdale, NJ: Lawrence Erlbaum.

³⁰Our belief in the importance of perceived risk of experimental and occasional use led us to include in 1986 for the first time the question about the dangers of occasional use.

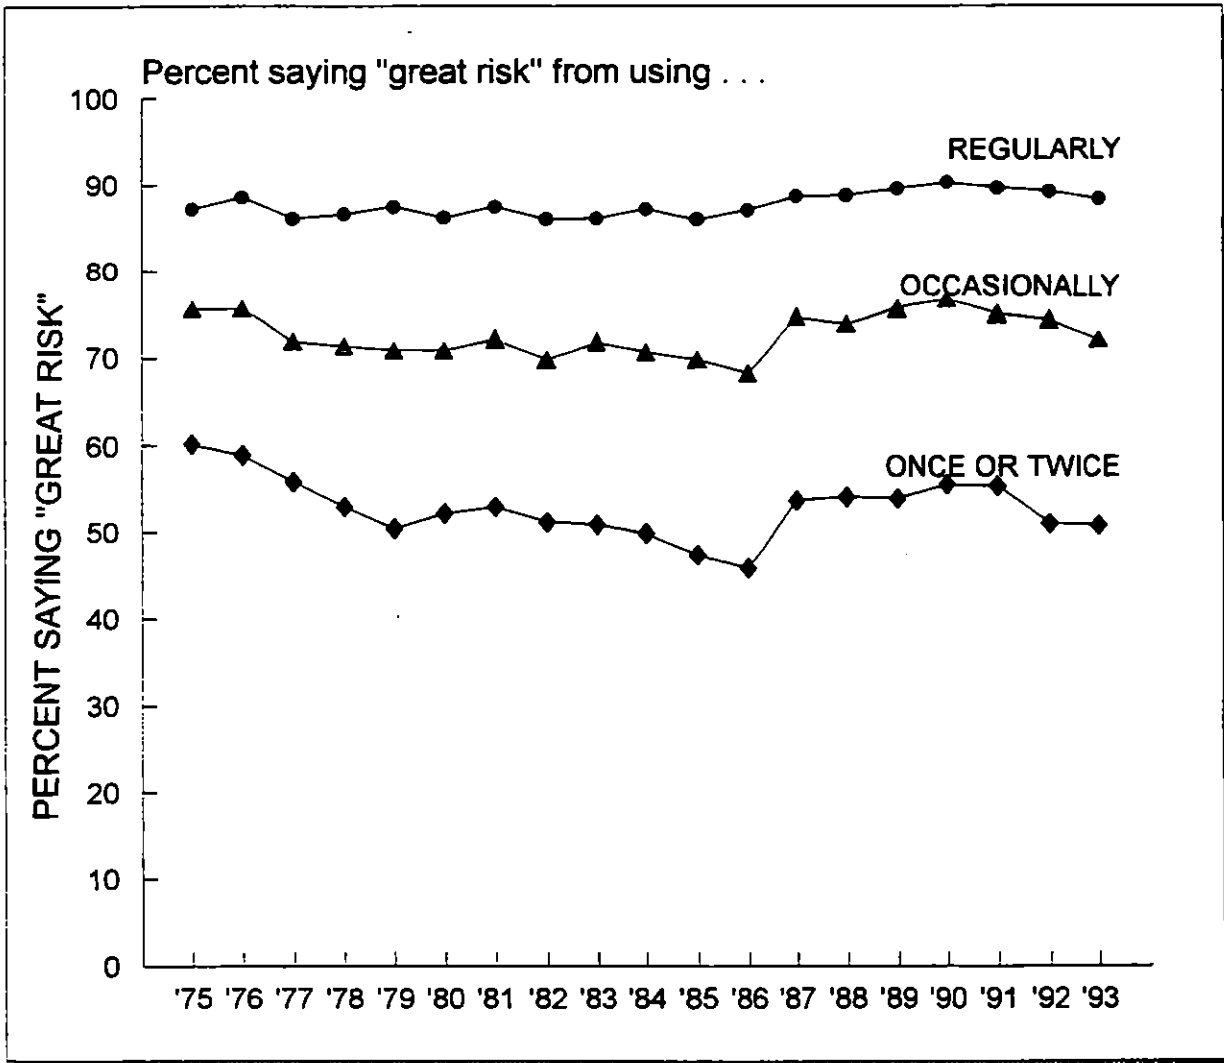

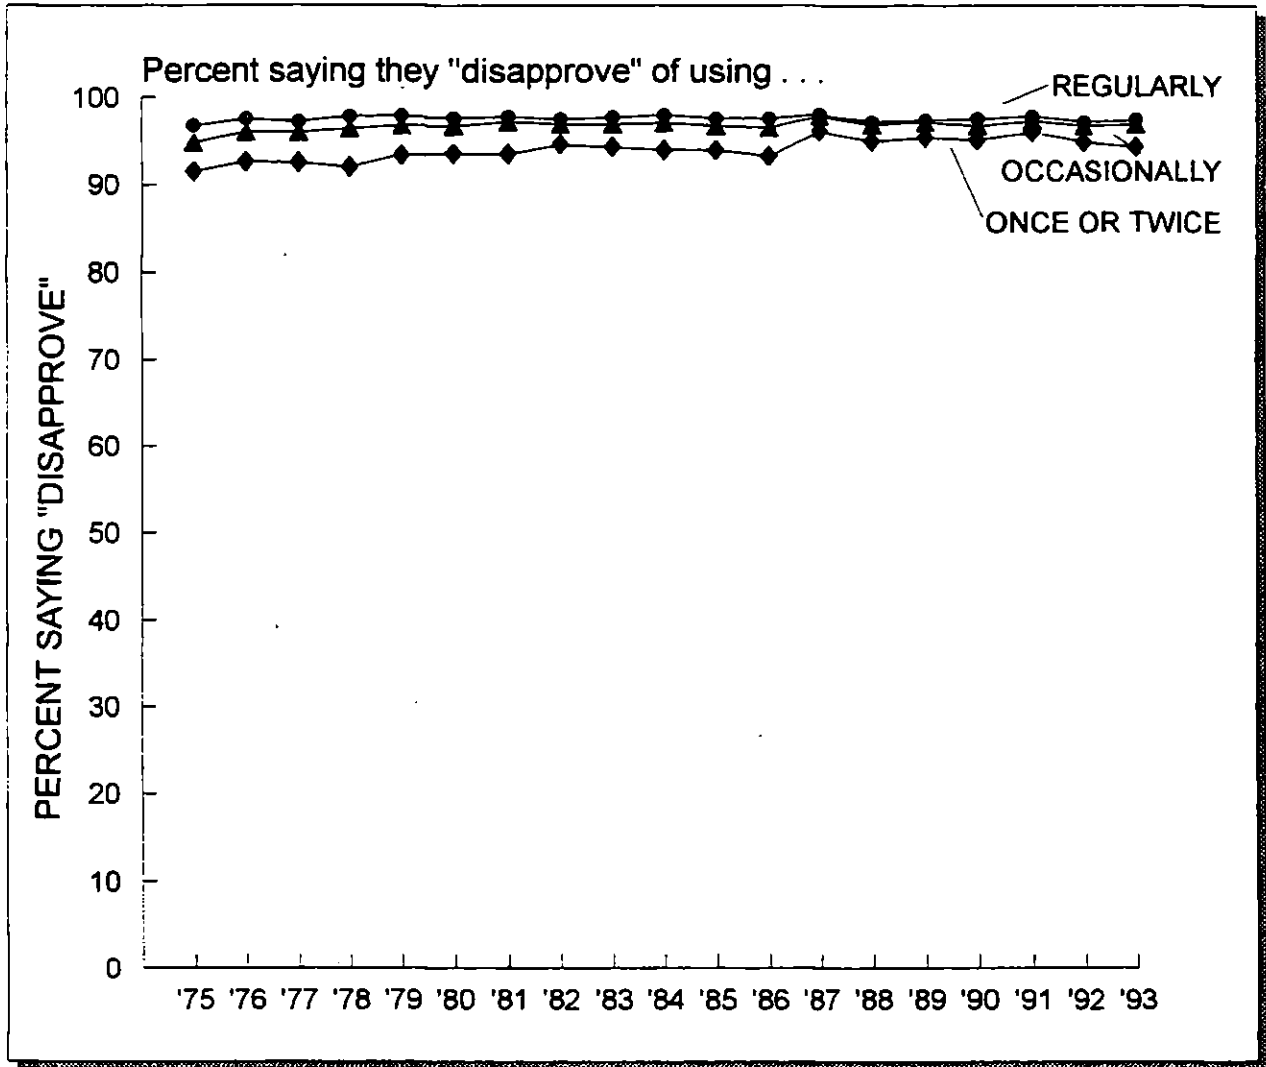

FIGURE 27b

Trends in Disapproval of Heroin Use for Twelfth Graders

perceived risk of experimental or occasional use increased for all drugs in 1987, reached a peak in 1990 or 1991, and began to decline significantly thereafter.

- Between 1975 and 1979 there was a distinct decline in perceived harmfulness associated with use of all the illicit drugs. After 1979, there was a dramatic increase in concerns about regular marijuana use, and a considerable increase in concerns about the use of marijuana at less frequent levels. After 1986 there was a sharp increase in the risks associated with cocaine use—particularly at the experimental and occasional use levels—and some increase in perceived risk for virtually all of the other illicit drugs, as well (Figures 25a, 26a, 27a). Since 1991, though, the trends have reversed and fewer seniors see them as dangerous.
- Particularly noteworthy, for *LSD* there was a sharp decline in perceived risk in 1992 and 1993, confirming our concern that the attitudes of the newer generation of young people may not have been influenced by some of the direct and vicarious learning experiences which helped to make their predecessors more cautious about this drug (Figure 26a). Recall that in the late 60s and early 70s young people became aware of the risks of bad trips, uncontrollable flashbacks, dangerous behaviors under the influence, etc. Today's youngsters know much less about all that.
- The risks associated with *barbiturate* use have fallen significantly since 1991, and with *crystal methamphetamine* (ice) since 1992.
- The perceived risk of *PCP*, though very high relative to other drugs in 1988, fell back by eight percentage points from its peak level in 1988 (59%) to 1993 (51%).
- After showing little systematic change in the latter half of the 1970s, the perceived risks associated with *alcohol use* at various levels rose during the 1980s (though not as dramatically as the perceived risks associated with marijuana and cocaine). The proportions perceiving great risk of harm in having one or two drinks nearly every day rose from 20% in 1980 to 28% in 1993. The proportions perceiving great risk in having four or five drinks nearly every day rose slightly from 66% to 68% over the same period, while the corresponding figures for *occasional binge drinking* (having five or more drinks once or twice a weekend) rose by more—from 36% to 48%. (Recall that the reported prevalence of occasional binge drinking declined in the same period, from 41% in 1980 to 28% in 1993.) These increases in perceived risk tended to be followed by some declines in the actual behaviors, once again suggesting the importance of these beliefs in influencing behavior.

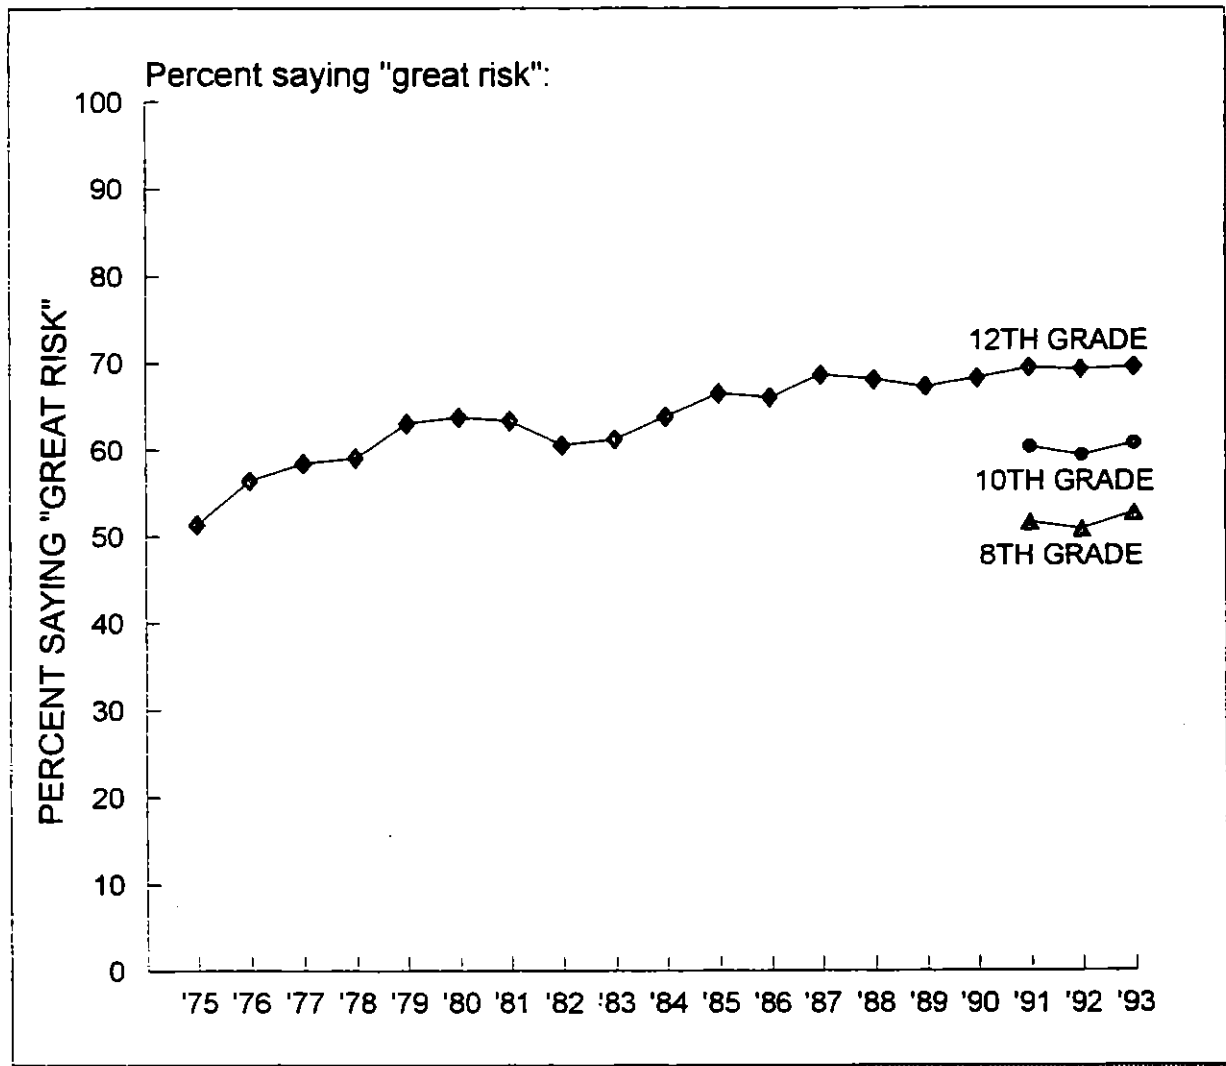

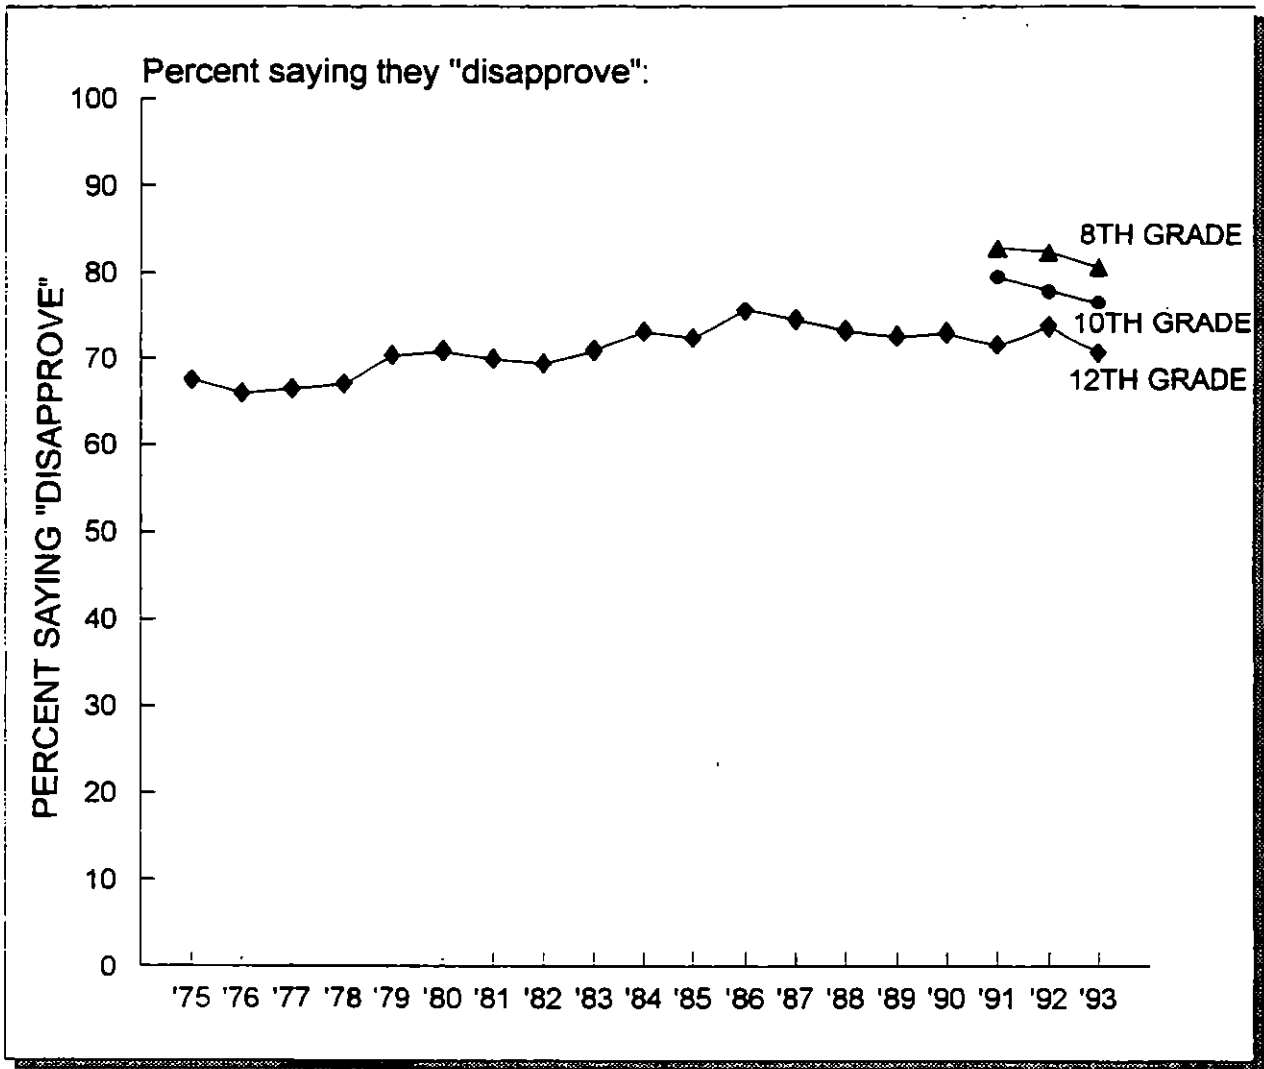

FIGURE 29b

**Trends in Disapproval of Smoking One or More Packs of Cigarettes per Day
for Eighth, Tenth, and Twelfth Graders**

Monitoring the Future

- Despite all that is known today about the health consequences of **cigarette smoking**, about one-third (31%) of twelfth grade students still do not believe that there is a great risk in smoking a pack or more of cigarettes per day.

Over a longer period, the number of seniors who thought **pack-a-day cigarette smoking** involved great risk to the user increased, from 51% in 1975 to 64% in 1980. This shift corresponded with, and to some degree preceded, the downturn in regular smoking found in this age group (compare Figures 9h and 29a). Between 1980 and 1984 this statistic showed no further increase, once again presaging the end of the decline in use. In the nine year interval since 1984, the percent of seniors perceiving great risk in regular smoking rose only about five percentage points.

As mentioned above, more younger children fail to recognize the risk associated with regular cigarette smoking. In 1993 perceived risk rose slightly (not significantly) among eighth and tenth graders, and their smoking rates rose as well.

Trends in Perceived Harmfulness Among Eighth and Tenth Graders

- Data for eighth and tenth graders are not available for many of the drugs on which there was a downturn in perceived risk among twelfth graders in 1993 (e.g., **LSD**, **heroin**, and **stimulants**). However, the eighth graders showed troublesome declines in perceived risk for the illicit drugs about which they were asked: **crack**, **cocaine powder**, and **marijuana** (see Table 19). Eighth graders showed significant declines in perceived risk for the regular use of **inhalants** in 1993, and tenth graders non-significant declines. (Inhalant questions are not asked of twelfth graders.)
- Because we see perceived risk as a central cause of the decline in various forms of illicit drug use, we mentioned last year that this softening in these beliefs was troublesome and could portend a reversal of the downward trends in illicit drug use. In 1993 marijuana and inhalant use did rise, and there is a likelihood that cocaine and crack use will rise by 1994.
- One noteworthy change in a constructive direction occurred across all three grade levels in 1992 for **steroids**. There were significant increases of between 5 and 6 percentage points across the three grade levels in respondents saying there is a "great risk" to the user in taking steroids. Between 70% and 73% of each grade level reported great risk. This suggested that the experience of professional football player, Lyle Alzado, which was widely publicized during that period, had an important effect on young people's beliefs about the damages of this

drug. The effect this "unfortunate role model" had was very similar to that of Len Bias on beliefs about the dangers of cocaine, except that in Lyle Alzado's case he became aware of the health consequences of his drug use well before his death, and *intentionally* set about making his experience an object lesson for young people.³¹ Unfortunately, this constructive development did not continue into 1993. There was little change in perceived risk at any grade level.

- The perceived risks of pack-a-day *cigarette smoking* has shown little change since 1991.

PERSONAL DISAPPROVAL OF DRUG USE

We developed a different set of questions to measure the moral sentiment respondents attach to various types of drug use. The phrasing, "Do you disapprove of people (who are 18 or older) doing each of the following" was adopted.

Extent of Disapproval Among Twelfth Graders

- The vast majority of seniors do not condone regular use of any of the illicit drugs (see Table 22). Even *regular marijuana use* is disapproved by 88%, and regular use of each of the other illicit drugs receives disapproval from between 93% and 98% of today's high school seniors.
- Fewer respondents indicate disapproval of experimental or occasional use than of regular use, for each of the drugs included in the question, as would be expected. The differences are not great, however, for the illicit drugs other than marijuana, because nearly all seniors disapprove even of experimentation. For example, 86% disapprove experimenting with *LSD*, 93% with *cocaine*, and 94% with *heroin*.
- For *marijuana*, the rate of disapproval varies substantially for different usage habits, although not as much as it did in the past. Some 63% disapprove of trying it versus 88% who disapprove of regular use.
- Smoking a pack (or more) of *cigarettes* per day now receives the disapproval of 71% of the age group.
- Taking *one or two drinks daily* is disapproved by 78% of the seniors. Curiously, *weekend binge drinking* (five or more drinks once or twice

³¹For a discussion of the importance of vicarious learning from unfortunate role models see Johnston, L.D. (1991). Toward a theory of drug epidemics. In R.L. Donohew, H. Sypher, & W. Bukoski (Eds.), *Persuasive communication and drug abuse prevention* (pp. 133-156). Hillsdale, NJ: Lawrence Erlbaum.

^bThe 1975 question asked about people who are "20 or older."

Monitoring the Future

each weekend) is acceptable to more seniors than is having one or two drinks daily. Only 70% disapprove of having five or more drinks once or twice a weekend in spite of the fact that more seniors associate great risk with weekend binge drinking (48%) than with having one or two drinks daily (28%).

One likely explanation for these anomalous findings may be that a greater proportion of this age group are themselves weekend binge drinkers rather than moderate daily drinkers. Therefore, they may express attitudes accepting of their own behavior, even though such attitudes may be somewhat inconsistent with their beliefs about possible consequences. It also may be that the ubiquitous advertising of alcohol use in "partying" situations has managed to increase acceptability from what it would be in the absence of such advertising.

Extent of Disapproval Among Eighth and Tenth Graders

- The rates of disapproval of drug use among the younger students are as high as, or higher than, they are among seniors (see Table 21).
- All three grade levels show very high and fairly comparable levels of disapproval for *cocaine powder* and *crack*.
- The same is true for the use of *steroids*.
- Attitudes about *inhalant* use have been asked only of the eighth and tenth grade students, 83% and 85% respectively, say they disapprove of trying them.
- *Marijuana* shows the greatest age-related difference in disapproval rates. The rates of disapproval of marijuana use increase as one moves down in grade level. To illustrate, 63% of twelfth graders disapprove of trying marijuana, 70% of tenth graders, and 79% of eighth graders. There may, of course, be some tendency for these attitudes to shift with age, but it is also possible that these differences reflect some important differences between class cohorts.
- Disapproval of *alcohol* use also increases as one moves down in grade level. For example, 70% of the seniors, 75% of the tenth graders, and 83% of the eighth graders disapprove of weekend binge drinking. Because of the shifts in the minimum drinking ages in a number of states, we think it quite possible that a cohort shift in attitudes about drinking had been taking place, since for the younger cohorts teenage drinking has been illegal for a greater proportion of their lives.
- Similarly, for *cigarette* use, 71% of seniors, 77% of tenth graders, and 81% of eighth graders disapprove of smoking one or more packs per

day. Oddly enough, the eighth graders, who are least likely to see regular smoking as dangerous, are the most likely to disapprove of it.

TRENDS IN DISAPPROVAL OF DRUG USE

Trends in Disapproval Among Twelfth Graders

- Between 1975 and 1977 a substantial decrease occurred in disapproval of *marijuana* use at any level of frequency (see Table 22, and Figure 21b). About 14% fewer seniors in the class of 1977 (compared with the class of 1975) disapproved of experimenting, 11% fewer disapproved of occasional use, and 6% fewer disapproved of regular use. These undoubtedly were continuations of longer-term trends which began in the late 1960s, as the norms of American young people against illicit drug use were seriously eroded. Between 1977 and 1990, however, there was a very substantial reversal of that trend, with disapproval of experimental marijuana use having risen by 34 percentage points, disapproval of occasional use by 36 percentage points, and disapproval of regular use by 26 percentage points. There were no further significant changes in 1991 or 1992, though disapproval of experimental use continued to rise. In 1993, however, a sharp drop in disapproval of marijuana use emerged. Disapproval dropped 7% for experimental use, 4% for occasional use, and 3% for regular use. This change accompanied a significant increase in actual use.
- Until 1980 the proportion of seniors who disapproved of trying *amphetamines* had remained extremely stable (at 75%). This proportion dropped slightly in 1981 (to 71%), but increased thereafter and reached 87% in 1991. Again, there was no further change in 1992, but in 1993 a reversal emerged. Disapproval dropped by nearly 3%, and actual use increased.
- During the late 1970s, personal disapproval of experimenting with *barbiturates* increased (from 78% in 1975 to 84% in 1979) and remained relatively stable through 1984, when it began to increase again. By 1990 disapproval had reached 91% and has changed little since.
- Concurrent with the years of increase in actual *cocaine* use, disapproval of experimental use of cocaine declined somewhat, from a high of 82% in 1976 down to 75% in 1979 (Figure 22b). It then leveled for four years, edged upward for a couple of years to about 80% in 1986, and since then has risen significantly so that 93% of seniors now disapprove of trying cocaine. Again, there was no significant change in 1992 or 1993.

Monitoring the Future

- We believe that the parallel trends between perceived risk and disapproval—particularly for marijuana and cocaine—are no accident. As noted above, we hypothesize that perceived risk is an important influence on an individual's level of disapproval of a drug-using behavior, though there surely are other influences, as well. As levels of personal disapproval change, and these individually held attitudes are communicated among friends and acquaintances, perceived norms also change (as will be illustrated in the next chapter). It is noteworthy that as perceived risk for most of the illicit drugs began to reverse by 1991 or 1992, personal disapproval for virtually all of them appeared to level. In 1993, personal disapproval among seniors began to drop for nearly all of the illicit drugs (see Tables 20 and 22).
- Despite the large changes which seem to have taken place among adults, disapproval of *regular cigarette smoking* (a pack or more per day) has changed surprisingly little throughout this study. Disapproval increased from 68% to 71% between 1975 and 1980. During the 1980s and into the 1990s, disapproval rates fluctuated slightly, never exceeding 75%. In 1993 the disapproval rate is 71%. This lack of change is surprising because of all the anti-smoking laws and policies that have been enacted. Very likely, the efforts of the tobacco industry in promoting and advertising tobacco to young people help account for the lack of change in disapproval. It is worth noting that the disapproval rate among seniors in 1993 is the lowest it has been since 1982.
- Disapproval of alcohol use has risen gradually since 1980. Disapproval of weekend *binge drinking* has risen by 15 percentage points, from 56% in 1980 to a high of 71% in 1992, down slightly to 70% in 1993. The proportion of seniors who disapproved of even *trying alcohol* doubled, from a low point of 16% in 1980 to 33% in 1992, before falling back to 30% in 1993. It seems likely that the increased minimum drinking age in many states, which occurred primarily between 1981 and 1987, is contributing to these changes in attitude about abstention, since most seniors today grew up under the higher minimum drinking age. If so, this illustrates the considerable capacity of laws to influence informal norms.

Trends in Disapproval Among Eighth and Tenth Graders

Table 21 provides the two-year trends (1991-1993) in disapproval, which is all that is available for the lower grade levels.

- In 1992 tenth and twelfth grade students showed little change in disapproval of the illicit drugs, but eighth graders did show some erosion in these attitudes with respect to *marijuana, cocaine powder, and crack*. In 1993, rates of disapproval for these drugs

continued to decline among eighth graders and began to decline among tenth and twelfth graders as well (Table 21).

- The declines in personal disapproval have been particularly sharp for *marijuana* at all three grade levels.
- The softening in attitudes about *cocaine powder* and *crack* have not yet translated into a change in usage levels, but this is a distinct possibility by the time of the next survey.
- Because *LSD* was added to the eighth and tenth grade questionnaire in 1993, no trend data are yet available. The twelfth graders did show some, not quite statistically significant, decline in the proportion disapproving LSD experimentation.
- The widespread nature of the 1993 downturns in disapproval of use is disturbing because it could indicate a larger shift in norms and in use.
- Disapproval of weekend *binge drinking* has declined significantly among eighth and tenth graders since 1991. It leveled among twelfth graders in 1993.
- Disapproval of *cigarette smoking* has also declined significantly since 1991 among eighth and tenth graders. It began to fall in 1993 among twelfth graders.

ATTITUDES REGARDING THE LEGALITY OF DRUG USE

At the beginning of the study, legal restraints on drug use appeared likely to be in a state of flux for some time; therefore, we decided to measure attitudes about legal sanctions. As it turns out, some dramatic changes in these attitudes have occurred during the life of the study. Table 23 presents a set of questions on this subject along with the answers provided by each senior class. The set lists a sampling of illicit and licit drugs and asks whether their use should be prohibited by law. A distinction is consistently made between use in public and use in private—a distinction which proved quite important in the results. (These questions have not been asked of the eighth and tenth grade respondents.)

Attitudes of Twelfth Graders

- The great majority of seniors believe that the use in public of *illicit drugs other than marijuana* should be prohibited by law. For instance, in the case of amphetamines or barbiturates, 78% of the seniors believed that use should be prohibited, and 85% believe heroin should be prohibited.
- The great majority of seniors (77%) also favor legally prohibiting *marijuana* use in public places, despite the fact that almost one-third

^aAnswer alternatives were: (1) No, (2) Not sure, and (3) Yes.
^bThe 1975 question asked about people who are "20 or older."

have used marijuana themselves, and despite the fact that many do not judge it to be as dangerous a drug as the others. Considerably fewer (48%) feel that marijuana use in private should be prohibited.

- Some 46% of twelfth graders believe that *cigarette* smoking in public places should be prohibited by law. Slightly more think *getting drunk* in such places should be prohibited (54%).
- For *all drugs*, fewer seniors believe that use in private settings should be illegal. This is particularly true for alcohol and marijuana.

Trends in These Attitudes Among Twelfth Graders

- From 1975 through 1977 there was a modest decline (shifts of 4% to 7%, depending on the substance) in the proportion of seniors who favored legal prohibition of private use of *any of the illicit drugs*. By 1990, however, all of these proportions had increased.
- Over the thirteen year interval, from 1977 to 1990, there was an appreciable rise in the proportion favoring legal prohibition of *marijuana* use, either in private (up from 27% to 56%) or in public (up from 59% to 82%).
- For other illicit drugs, (*LSD*, *heroin*, *amphetamines*, and *barbiturates*), the changes were more modest, because the rates were quite high already. Between 1977 and 1990 all showed increased proportions favoring prohibition.
- Since 1990, there has been some softening of seniors' positions on all of the illegal drugs. For instance, the proportion favoring prohibitions on the use of *marijuana* in public fell from 82% to 77%, and in private from 56% to 48% by 1993.
- There has been rather little change in the proportion of seniors who say *smoking cigarettes* in certain specified public places should be prohibited by law. In 1977 some 42% held this view vs. 43% in 1985, and 46% in 1993. Were the question more specific as to the places in which smoking might be prohibited (e.g., hospitals, restaurants, etc.) different results might emerge.
- There has been little change in seniors' preferences about the illegality of *drunkenness* in public or private places, though what change has occurred has been in the direction of less tolerance of these behaviors. The stability of attitudes about the preferred legality for this culturally ingrained drug-using behavior contrasts sharply with the lability of preferences regarding the legality of the illicit drugs.

THE LEGAL STATUS OF MARIJUANA

Another set of questions goes into more detail about what legal sanctions, if any, seniors think should be attached to the use and sale of marijuana. Respondents also are asked to guess how they would be likely to react to legalized use and sale of the drug. While the answers to such a hypothetical question must be interpreted cautiously, a special study of the effects of marijuana decriminalization at the state level, conducted as part of the Monitoring the Future series, suggests that in the aggregate their predictions about how they would react proved relatively accurate.³²

Attitudes and Predicted Responses to Legalization

- As shown in Table 24, in 1993 less than half (43%) of all seniors believe that marijuana use should still be treated as a crime. Almost one-quarter think it should be entirely legal (23%), about another one-fifth (19%) feel it should be treated as a minor violation—like a parking ticket—but not as a crime. Another 15% indicate no opinion.
- Asked whether they thought it should be legal to sell marijuana if it were legal to use it, about half (51%) said "yes." However, nearly all of these respondents would permit sale *only* to adults.
- High school seniors predict that they would be little affected personally by the legalization of either the sale or the use of marijuana. Over two-thirds (69%) of the respondents say that they would not use the drug even if it were legal to buy and use, and another 13% indicate they would use it about as often as they do now, or less. Only 4% say they would use it more often than at present and only another 7% think they would try it. Some 7% say they do not know how they would react.

The special study of the effects of decriminalization at the state level during the late 1970s (which falls well short of the fully-legalized situation posited in this question) revealed no evidence of any impact of decriminalization on the use of marijuana, nor even on attitudes and beliefs concerning its use. On the other hand, the times today are very different, with more peer disapproval and more rigorous enforcement, and the symbolic message of legalizing or decriminalizing marijuana would likely be different, as well. Therefore, we do not believe that those findings from the late 1970s can be validly generalized to the legalization of marijuana today.

Trends in Attitudes and Predicted Responses

- In recent years American young people have become much more supportive of legal prohibitions on the use of illegal drugs, whether used in private or in public.
- Between 1976 and 1979 seniors' preferences for decriminalization or legalization remained fairly constant; but between 1979 and 1990 the proportion favoring outright legalization dropped by almost half (from 32% in 1979 to 16% in 1990), while there was a corresponding doubling in the proportion saying marijuana use should be a crime (from 24% to 53%). Also reflecting this increased conservatism about marijuana, somewhat fewer said they would support legalized *sale*, even if *use* were made legal (down from 65% in 1979 to 48% in 1990).
- Since 1990 these policy attitudes have begun to soften again. Fewer favor criminal penalties and more favor legal sale (see Table 24). For example, in 1993, the proportion saying that using marijuana should be entirely legal is 23%, the highest figure since 1991.
- The predictions about personal marijuana use, if sale and use were legalized, have been quite similar for all high school classes. The slight shifts being observed are mostly attributable to the changing proportions of seniors who actually use marijuana.
- As with all of the other attitudes and beliefs examined in this chapter, the long term anti-drug changes appeared to level or reverse in 1991, 1992, and 1993.

Chapter 9

THE SOCIAL MILIEU

The preceding chapter dealt with students' own attitudes about various forms of drug use. Attitudes about drugs, as well as drug-related behaviors, obviously do not occur in a social vacuum. Drugs are discussed in the media; they are a topic of considerable interest and conversation among young people; they are also a matter of much concern to parents, concern which often is strongly communicated to their children. Young people are known to be affected by the actual drug-taking behaviors of their friends and acquaintances, as well as by the availability of the various drugs. This section presents data on several of these relevant aspects of the social milieu.

We begin with two sets of questions about parental and peer attitudes, questions which closely parallel the questions about respondents' own attitudes about drug use, discussed in the preceding chapter. Since measures of parental attitudes have not been carried in the study in recent years, those mentioned here are based on the much earlier 1979 results.

PERCEIVED ATTITUDES OF PARENTS AND FRIENDS: TWELFTH GRADERS

Perceptions of Parental Attitudes

- Even at the height of the drug epidemic in 1979, a large majority of seniors felt that their parents would disapprove or strongly disapprove of their exhibiting *any of the drug use behaviors* which are listed in Table 25. (The data for the perceived parental attitudes are not given in tabular form, but are displayed in Figures 30a and 30b and 31.) In fact, because there was so little variability in the students' answers to these questions, they were dropped to make room for other questions. With the changing climate in recent years, as exemplified by the dramatic shifts in students' attitudes, it seems likely that parental attitudes would be even more restrictive today.
- Drug use appears to constitute one area in which the position of parents approaches complete unanimity. In 1979, over 97% of seniors said that their parents would disapprove or strongly disapprove of their smoking *marijuana* regularly, even trying *LSD* or *amphetamines*, or having four or five *drinks* every day. (Although the questions did not include more frequent use of LSD or amphetamines, or any use of heroin, it is obvious that if such behaviors had been included in the list virtually all seniors would have indicated parental disapproval.)
- Even experimental use of *marijuana* was seen as a parentally disapproved activity by the great majority of the 1979 seniors (85%). Assuming that the students were generally correct about their parents'

Monitoring the Future

attitudes, these results clearly showed a substantial generational difference of opinion about this drug.

- Also likely to be perceived as rating high parental disapproval (91-93% disapproval) were *occasional marijuana* use, taking *one or two drinks* nearly every day, and *pack-a-day cigarette smoking*.
- Slightly lower proportions of seniors (85%) felt their parents would disapprove of their having *five or more drinks once or twice every weekend*. This happened to be the same percentage as said that their parents would disapprove of simply experimenting with marijuana, showing a considerably more tolerant parental attitude toward alcohol than marijuana.

Perceptions of Friends' Attitudes

- Since the beginning of the study, a parallel set of questions has asked respondents to estimate their friends' attitudes about drug use (Table 25). These questions ask, "How do you think your close friends feel (or would feel) about you [taking the specified drug at the specified level]...?" The highest levels of peer disapproval in 1993 for experimenting with a drug are associated with trying *crack* (95%), *cocaine powder* (94%), *LSD* (84%), and *amphetamines* (83%). Presumably, if *heroin* or *PCP* were on the list, they too would receive very high peer disapproval.
- Even experimenting with *marijuana* now is viewed with disapproval by most seniors' friends (67%); and a large majority think their friends would disapprove if they smoked marijuana regularly (84%).
- Nearly three-quarters of all seniors think they would face peer disapproval if they smoked a *pack or more of cigarettes daily* (72%).
- While *heavy drinking on weekends* is judged by more than half (59%) to be disapproved of by their friends (many of whom exhibit that behavior themselves), substantially more (77%) think consumption of *one or two drinks daily* would be disapproved, and the great majority (87%) would face the disapproval of their friends if they engaged in *heavy daily drinking*.
- In sum, peer norms among twelfth grade students differ considerably for the various drugs and for varying degrees of involvement with those drugs, but overall they tend to be quite conservative. The great majority of seniors have friendship circles which do not condone use of the *illicit drugs other than marijuana*, and two-thirds (67%) of them now believe their friends would disapprove of their even trying marijuana.

NOTE: The 1975, 1977, and 1979 points indicating the percentage of seniors who said their friends would disapprove have been adjusted to compensate for lack of comparability of question-context between administration years. (See text for discussion.)

- While we did not have the space to include these questions in the eighth and tenth grade questionnaires (for which there are only two forms instead of six) there seems little doubt that they would report at least as restrictive peer norms as the twelfth graders, and perhaps more restrictive ones, based on the cross-grade comparisons of personal disapproval, given in Chapter 8.

A Comparison of the Attitudes of Parents, Peers, and Twelfth Graders

A comparison of seniors' perceptions of friends' disapproval with their perceptions of parents' disapproval, in the years for which comparison is possible, showed several interesting findings.

- First there was rather little variability from year to year in students' perceptions of their parents' attitudes. On any of the drug behaviors listed nearly *all* said their parents would disapprove. Nor was there much variability among the different drugs in perceived parental attitudes. However, peer norms varied much more from drug to drug. From these facts we may conclude that peer norms have a much greater chance of explaining variability in the respondent's own individual attitudes or use than parental norms, simply because the peer norms vary more. We wish to emphasize that this is quite different than saying that parental attitudes do not matter, or even that they matter less than peer attitudes.
- Despite less variability in parental attitudes, the *ordering* for disapproval of drug use behaviors was much the same as for peers. That is, among the illicit drugs asked about, the highest frequencies of perceived disapproval were for trying cocaine, while the lowest frequencies were for trying marijuana.
- A comparison with the seniors' own attitudes regarding drug use reveals that on the average they are much more in accord with their peers than with their parents (see Figures 30a, 30b, and 31). The differences between seniors' own disapproval ratings in 1979 and those attributed to their parents tended to be large, with parents seen as more conservative overall in relation to *every drug*, licit or illicit. The largest difference occurred in the case of *marijuana* experimentation, where only 34% of seniors in 1979 said they disapproved vs. 85% who said their parents would disapprove. Despite the near doubling in seniors' own disapproval rates (to 63% in 1993), it remains the most controversial of the illicit drug-using behaviors listed here.

Trends in Perceptions of Parents' and Friends' Attitudes

Several important changes in twelfth graders' perceptions of their peers' attitudes have been taking place. These shifts are presented graphically in Figures 30a, 30b, and 31. As can be

seen in those figures, adjusted (dotted) trend lines have been introduced before 1980. This was done because we discovered that the deletion in 1980 of the questions about parents' attitudes—which, up until then, had been located immediately preceding the questions about friends' attitudes—removed what we judged to be an artifactual depression of the ratings of friends' attitudes, a phenomenon known as a question-context effect. This effect was particularly evident in the trend lines dealing with alcohol use, where otherwise smooth trend lines showed abrupt upward shifts in 1980. It appears that when questions about parents' attitudes were present, respondents tended to understate peer disapproval in order to emphasize the *difference* in attitudes between their parents and their peers. In the adjusted lines, we have attempted to correct for that artifactual depression in the 1975, 1977, and 1979 scores.³³ We think the adjusted trend lines give a more accurate picture of the change taking place. Note that the question-context effect seems to have had more influence on the questions dealing with cigarettes and alcohol than on those dealing with illicit drugs.

- For each level of *marijuana* use—trying once or twice, occasional use, regular use—there had been a drop in perceived disapproval for both parents and friends up until 1977 or 1978. We know from our other findings that these perceptions correctly reflected actual shifts in the attitudes of their peer groups—that is, that acceptance of marijuana was in fact increasing among seniors (see Figures 30a and 30b). There is little reason to suppose such perceptions are less accurate in reflecting shifts in parents' attitudes. Therefore, we conclude that the social norms regarding marijuana use among adolescents and adults had been relaxing before 1979. However, consistent with the seniors' reports about their own attitudes, there was a sharp reversal in peer norms (and very likely adult norms, as well) regarding all levels of marijuana use. Peer disapproval of marijuana use continued to increase significantly through 1992, as did personal disapproval. In 1993 a sharp reversal occurred, with the percent of seniors saying that their friends would disapprove dropping from 5-7 percentage points, depending on the level of use about which the question asks.
- Until 1979 there had been relatively little change in either self-reported attitudes or perceived peer attitudes toward *amphetamine* use, but in 1981 both measures showed significant and parallel dips in disapproval as use rose sharply. Since 1981 disapproval has been rising, as use has declined. In 1993 peer disapproval again declined as use increased significantly, though the shift in norms was not as sharp as for marijuana.

³³The correction evolved as follows: We assumed that a more accurate estimate of the true change between 1979 and 1980 could be obtained by taking an average of the changes observed in the year prior and the year subsequent, rather than by taking the observed change (which we knew to contain the effect of a change in question context). We thus calculated an *adjusted* 1979-1980 change score by taking an average of one-half the 1977-1979 change score (our best estimate of the 1978-1979 change) plus the 1980-1981 change score. This estimated change score was then subtracted from the observed change score for 1979-1980, the difference being our estimate of the amount by which peer disapproval of the behavior in question was being understated because of the context in which the questions occurred prior to 1980. The 1975, 1977, and 1979 observations were then adjusted upward by the amount of that correction factor.

- Peer disapproval of *LSD*, which has been high and relatively stable for some years, also decreased significantly in 1993 as use increased significantly. In fact, the peak level for *LSD* was back in 1988, when 90% said their friends would disapprove trying it. By 1993 this statistic had fallen to 84% with nearly a 4% drop in 1993 alone.
- While perceived attitudes of friends was not asked for *cocaine* (until 1986), or for *barbiturates*, it seems likely that such perceptions moved in parallel to the seniors' own attitudes, since such parallel movement has been observed for virtually all other drugs (see Figures 30a and 30b). In fact, peer disapproval of cocaine use has been roughly parallel to seniors' disapproval since 1986. This also would suggest that disapproval has risen gradually but steadily for *barbiturate* use since 1975.
- Regarding experimenting with *cocaine*, seniors' own disapproval dropped from 1975 to 1979, but then rose very gradually through 1992. Questions on perceived attitudes of friends for experimental and occasional use of cocaine were added in 1986. Between 1986 and 1992 a sharp increase in peer disapproval of experimental or occasional cocaine use is shown, with the proportion saying that their close friends would disapprove of their experimenting with cocaine rising from 80% in 1986 to 92% in 1992. This corresponds to the period in which an even larger increase in perceived risk occurred, and we hypothesize that the change in the perceived dangers of a drug contribute to changes in the acceptability of using that drug.³⁴ In 1993, all of these variable began to reverse, unfortunately.
- Regarding *regular cigarette smoking*, the proportion of seniors saying that their friends would disapprove of them smoking a pack-a-day or more rose from 64% (adjusted) in 1975 to 74% in 1980. During the twelve-year period between 1980 and 1992, perceived peer disapproval fluctuated by only a few percentage points. It then dropped significantly from 76% in 1992 to 72% in 1993.
- For alcohol the perceived peer norms for *weekend binge drinking* moved pretty much in parallel with seniors' statements about their personal disapproval through 1985. This meant a slight decline in disapproval in the mid-1970s followed by a period of little change through 1984. Since then, some divergence appears to have occurred, with seniors' reports of their own attitudes becoming less tolerant as perceived peer norms took longer to begin an upward trend. This would

³⁴Johnston, L.D. (1991) Toward a theory of drug epidemics. In R.L. Donohew, H. Sypher, & W. Bukoski (Eds.), *Persuasive communication and drug abuse prevention* (pp. 93-132). Hillsdale, N.J.: Lawrence Erlbaum.

suggest that there may be some "collective ignorance" of the extent to which peers disapprove of this activity.

- **Heavy daily drinking** is seen by the great majority (87% in 1993) as disapproved by peers, with little systematic change over more than a decade. Taking one or two drinks nearly every day has seen some growth in peer disapproval since 1987.

FRIENDS' USE OF DRUGS

It is generally acknowledged that much of youthful drug use is initiated through a peer social-learning process; and research has shown a high correlation between an individual's illicit drug use and that of his or her friends. Such a correlation can, and probably does, reflect several different causal patterns: (a) a person with friends who use a drug will be more likely to try the drug; (b) conversely, the individual who is already using a drug will be likely to introduce friends to the experience; and (c) users are more likely to establish friendships with others who already are users.

Given the potential importance of exposure to drug use by others, we felt it would be useful to monitor students' association with others taking drugs, as well as their perceptions about the extent to which their friends use drugs. Two sets of questions, each covering all or nearly all of the categories of drug use treated in this report, asked seniors to indicate (a) how often, during the past twelve months they were around people taking each of the drugs to get high; or for "kicks," and (b) what proportion of their own friends use each of the drugs. (The data dealing with direct exposure to use may be found in Table 26. The questions dealing with friends' use are shown in Tables 27 and 28.) Obviously, responses to these two questions are highly correlated with the respondents' own drug use; thus, for example, seniors who have recently used marijuana are much more likely to report that they have been around others getting high on marijuana, and that most of their friends use it. The questions on proportions of friends using the various drugs also were added to the questionnaires used with eighth and tenth graders and the results for those age groups will be discussed in a separate section below.

Exposure to Drug Use by Friends and Others: Twelfth Graders

- A comparison of the aggregated responses about friends' use and about being around people in the last twelve months who were using various drugs to get high reveals a high degree of correspondence between these two indicators of exposure. (These two questions appear on separate forms of the questionnaire.) For each drug, the proportion of respondents saying "none" of their friends use it is fairly close to the proportion who say that during the last twelve months they have not been around anyone who was using that drug to get high. Similarly, the proportion saying they are "often" around people getting high on a given drug is roughly the same as the proportion reporting that "most" or "all" of their friends use that drug.

TABLE 26

Trends in Twelfth Graders' Exposure to Drug Use

*These estimates were derived from responses to the questions listed. "Any illicit drug" includes all of the drugs listed except MDMA (ecstasy), cocaine powder, crystal methamphetamine (lco), alcohol, cigarettes, and steroids. PCP and the nitrites were not included in 1975 through 1978. Crack was not included in 1976 through 1986.

SOURCE: The Monitoring the Future Study, the University of Michigan.

- As would be expected, reports of exposure and friends' use closely parallel the figures on seniors' own use (compare Figures 2 and 32). It thus comes as no surprise that the highest levels of exposure involve **alcohol**; a majority (52%) say they are "often" around people using it to get high. What *may* come as a surprise is that fully 28% of all seniors say that most or all of their friends go so far as to **get drunk** at least once a week. (This is consistent, however, with the fact that 28% said they personally had taken five or more drinks in a row at least once during the prior two weeks.)
- Students are exposed next most frequently to **marijuana**. More than half of the twelfth graders (61%) report some exposure during the year. Some 21% are "often" around people using it to get high, and another 18% are exposed "occasionally." One in seven (14%) now say that most or all of their friends smoke marijuana.
- **Amphetamines** are next with 25% of seniors reporting some exposure to use in the prior year, and 28% saying they have friends who use.
- Of all seniors, 19% have been around someone using **cocaine** to get high over the past year, and a quarter (25%) say they have some friends who use it.
- For the remaining illicit drugs, any exposure to use in the past year ranges from 21% for **LSD** down to 6% for **heroin**.
- The majority of seniors (57%) report no exposure to **illicit drugs other than marijuana** during the prior year, but only a third (34%) report no exposure to **any illicit drug** during the year. Thus, exposure to **marijuana** use, at least, is still widespread, but exposure to the use of **drugs other than marijuana** occurs for "only" 43%.
- Regarding **cigarette smoking**, one in every four seniors (25%) reports that most or all of his or her friends smoke, and 85% have at least some friends who smoke.

Friends' Use of Drugs: Eighth and Tenth Graders

While the questions about exposure to use were not included in the questionnaires for grades 8 and 10, the questions regarding the proportion of their friends who use each drug were included.

- As would be expected, eighth and tenth grade students are considerably less likely to have friends who use the various drugs than twelfth graders (Table 28). For example, for **cocaine powder**, **crack**, and **heroin** fewer than 13% of the eighth graders and fewer than 16% of the tenth graders have any friends who use.

FIGURE 32

Proportion of Friends Using Each Drug
as Estimated by Eighth, Tenth, and Twelfth Graders, 1993

FIGURE 32 (cont.)

Proportion of Friends Using Each Drug
as Estimated by Eighth, Tenth, and Twelfth Graders, 1993

Monitoring the Future

- For ***marijuana***, however, nearly a third (31%) of the eighth graders and half (53%) of the tenth graders have friends who use.
- Almost as many eighth graders (26%) have friends who use ***inhalants***, but by tenth grade many fewer have friends who use inhalants (21%) than use marijuana (53%).
- Exposure to ***alcohol*** use through friends is much more widespread, with three-quarters (76%) of the eighth graders and 92% of the tenth graders having friends who use. In fact, one-fourth (26%) of the eighth graders and one-half (50%) of the tenth graders say that most or all of their friends ***drink***, and the proportions saying that most or all of their friends ***get drunk*** at least once a week is one in eleven (9%) and one in five (20%), respectively.
- Exposure to ***cigarette smoking*** through friends also is very high for these children, with three-quarters (74%) of the eighth graders and 85% of the tenth graders saying they have some friends who smoke.

TRENDS IN FRIENDS' USE OF DRUGS

Trends in Exposure to Drug Use by Friends and Others: Twelfth Graders

- During the two-year interval from 1976 to 1978, seniors' reports of exposure to ***marijuana*** use increased in just about the same proportion as percentages of actual monthly use. In 1979 both exposure to use and actual use stabilized, and since 1979 both dropped steadily for some years. The proportion saying they are often around people using marijuana decreased by more than half by 1992, from 39% in 1979 to 16%. In 1993 there was a significant increase in such exposure rising to 21%. Recall that self-reported use also rose sharply in 1993.
- ***Cocaine*** showed a consistent increase from 1976 to 1979 in the proportion of seniors exposed to users, as self-reported use rose. From 1979 to 1984 there was little change in exposure to use coinciding with a period of stability in self-reported use; and in 1985 and 1986 there was some increase in reported exposure to use. These were also the peak years in self-reported use. After 1986 the seniors' exposure to cocaine use began dropping steadily, and the proportion saying they had any friends who use dropped from 46% in 1986 to 26% in 1992. In fact, in the two year interval from 1989 to 1992, this statistic dropped eleven percentage points. In 1993, use stabilized, as did the statistics on exposure to use and friends' use.

- **Inhalant** use by friends has shown some increase since 1983, with the proportion reporting having any friends who use rising from 16% in 1983 to 19% in 1991, and then rising more quickly to 24% in 1993. (A question on exposure to inhalant use is not asked.)
- From 1979 to 1989 there was a gradual decrease in exposure to the use of **psychedelics other than LSD** which coincided with a continued decline in the self-reported use of this class of drugs. Between 1989 and 1992, friends' use remained fairly stable, but in 1993 exposure increased, as did self-reported use.
- Exposure to **tranquilizer** use generally has been declining gradually since 1976, as has actual use. In 1993, however, use rose as did reported exposure (though not by a statistically significant amount).
- There was also a gradual decrease in exposure to **barbiturates** and **LSD**, from 1975 through 1980. Then exposure to the use of both of these drugs remained level for two years, as did the usage figures. After that, barbiturates generally have shown a continuing decline in both use and exposure to use. Friends' use of LSD reached a low point by about 1985 and remained stable through 1991. In 1992 and 1993, there were significant increases in the proportion of twelfth graders who said they had some friend(s) who used. While the proportion who said they were exposed to use grew more gradually from 1988 to 1992 there was a significant increase in this proportion in 1993.
- Trend data are available only since 1979 on friends' use of **PCP** or the **nitrites**. For both drugs, exposure to friends' use dropped significantly between 1979 and 1983. Only half as many twelfth graders in 1983 (14%) said any of their friends used PCP compared with twelfth graders in 1979 (28%). The corresponding drop for nitrites was from 22% to 15%. Since 1983 there has been some further decrease in exposure for both drugs, though exposure to friends' use of PCP increased significantly in 1993.
- The proportion having any friends who used **amphetamines** rose from 41% to 51% between 1979 and 1982, paralleling the sharp increase in reported use over that period. The proportion saying they were around people using amphetamines "to get high or for kicks" also jumped substantially between 1980 and 1982 (by 9% to 50%).³⁵ It then fell continually by a full 26 percentage points between 1982 and 1992 as self-reported use declined substantially until 1992. In 1993, self-

³⁵This finding was important, since it indicated that a substantial part of the increase observed in self-reported amphetamine use was due to things other than simply an increase in the use of over-the-counter diet pills or stay-awake pills, which presumably are not used to get high. Obviously, more young people were using stimulants for recreational purposes. There still remained the question, of course, of whether the active ingredients in those stimulants really were amphetamines.

Monitoring the Future

reported use increased significantly and exposure to use increased very slightly.

- Between 1978 and 1981 *methaqualone* use rose, as did the proportion of seniors saying some of their friends used it. A decline in both seniors' use and friends' use started in 1982, and by 1993 the proportion of seniors saying they had any friends who use quaaludes fell by more than half (down from 35% to 14% between 1981 and 1993). Seniors' usage rates showed a similar decline.
- The proportion saying that "most or all" of their friends smoke *cigarettes* dropped steadily and substantially between 1976 and 1981, from 37% to 22%. During this period self-reported use dropped markedly, and more seniors perceived their friends as disapproving regular smoking. Between 1982 and 1992, friends' use and self-reported use remained relatively stable; in fact, in 1992 the friends' use rate was close to the 1981 rate. In 1977, the peak year for actual use, 34% said most or all of their friends smoked; in 1981, 22%, and in 1992, 21%. In 1993 there was a significant increase in friends' use, to 25% as self-reported smoking also increased significantly.
- The proportion saying most or all of their friends *get drunk* at least once a week had been increasing steadily between 1976 and 1979, from 27% to 32%, in a period in which the prevalence of self-reported, occasional heavy drinking was rising by about the same amount. After that, there was little change in either measure for about five years. Beginning in 1984 and 1985, self-reports by seniors of their own heavy drinking began to decline; but reported heavy drinking by friends has shown a more modest decline. What remains the most impressive fact here, is that more than a quarter of all high school seniors (28% in 1993) say that most or all of their friends get drunk at least once a week. And only one in five (21%) say that none of their friends get drunk that often.

Implications for Validity of Self-Reported Usage Questions

We have noted a high degree of correspondence in the aggregate level data presented in this report among seniors' self-reports of their *own* drug use, their reports concerning *friends'* use, and their own *exposure* to use. Drug-to-drug comparisons in any given year across these three types of measures tend to be highly parallel, as are the changes from year to year.³⁶ We take this consistency as additional evidence for the validity of the self-report data, and of trends in the self-report data, since there should be less reason to distort answers on use by

³⁶Those minor instances of noncorrespondence may well result from the larger sampling errors in our estimates of these environmental variables, which are measured on a sample size one-fifth or one-sixth the size of the self-reported usage measures.

unidentified friends, or general exposure to use, than to distort the reporting of one's own use.

TRENDS IN FRIENDS' USE: EIGHTH AND TENTH GRADERS

Trend data for grades 8 and 10, presented in Table 28, are available only since 1991. In general, they show trends which are highly consistent with the trends in self-reported use at these grade levels. Note that these questions are asked of all respondents each year in grades 8 and 10, so the sample sizes are very large.

- In 1992 eighth graders showed increased self-reported use of a number of drugs (including *marijuana*, *inhalants*, *cocaine powder*, and *crack*), as well as in the proportion of their friends using them. In 1993, these trends continued among eighth graders, who were joined by tenth and twelfth graders in this turnaround. There were significant increases in use and in friends' use for *marijuana* and *inhalants* at all three grades (except that the change in inhalants did not reach significance among seniors).
- Among eighth and tenth graders, there were increases in the proportion of friends using *crack*, *cocaine powder*, and *heroin* (all but one reached significance), though there were no increases in use among seniors in 1993.
- The trends for using *alcohol* and *getting drunk* one or more per week are more complicated. Eighth graders report an increase in the proportions of their friends exhibiting these behaviors since 1991. Seniors show some decline over the same interval (most of it from 1991 to 1992), and tenth graders are in between, showing some increase in drunkenness by friends but no increase in the proportion of friends drinking.
- All three grades show an increasing proportion of friends *smoking* in 1993. For eighth and tenth graders this continues a trend from 1992. Recall that there were significant increases in smoking in all three grades.

PERCEIVED AVAILABILITY OF DRUGS

One set of questions asks respondents to estimate how difficult it would be to obtain each of a number of different drugs if they wanted them. The answers range across five categories

Monitoring the Future

from "probably impossible" to "very easy."³⁷ While no systematic effort has been undertaken to assess directly the validity of these measures, it must be said that they do have a rather high level of face validity, particularly if it is the subjective reality of "perceived availability" which is purported to be measured. It also seems quite reasonable to us to assume that perceived availability tracks actual availability to some extent.

Perceived Availability

- There are substantial differences in the reported availability of the various drugs. In general, the more widely used drugs are reported to be available by the highest proportion of the age group, as would be expected (see Table 29).
- The availability of *alcohol* and *cigarettes* was not even asked of seniors since we assume that these drugs are almost universally available to them. However, they are asked of the eighth and tenth graders, and even at these grade levels the availability is extremely high. *Cigarettes* are seen as most available: 76% of eighth graders and 89% of tenth graders think they would be "fairly easy" or "very easy" to get.
- *Alcohol* also is seen as readily available by the great majority of these youngsters, with 74% of the eighth graders and 89% of the tenth graders saying they could get it fairly easily or very easily.
- By contrast, the illicit drugs are seen as accessible by many fewer of the younger students. Still, *marijuana* is described as fairly easy or very easy to get by less than half (44%) of the eighth graders, followed by *amphetamines* (31%), *crack*, *cocaine powder*, and *barbiturates* (26%), *steroids* (23%), and *LSD* (22%).
- We assume that many *inhalants*—such as glues, butane, and aerosols—are universally available, and therefore, a question on their availability was not included.
- When we compare eighth, tenth, and twelfth grade, we find that perceived availability rises sharply with grade level. For example, while 44% of eighth graders say *marijuana* would be fairly easy or very easy to get, 68% of tenth graders say that, and 83% of the twelfth graders. In fact, for the other drugs included in the question, the proportion of students saying they are available to them nearly doubles between eighth grade and twelfth grade. These differences are probably attributable to the overall differences in prevalence rates

³⁷In the questionnaire used with eighth and tenth graders, an additional answer category of "can't say, drug unfamiliar" is offered; respondents who chose this answer are included in the calculation of percentages. Generally less than 20% of the respondents selected this answer.

NOTES: Level of significance of difference between the two years: s = .05, ss = .01, sss = .001. '—' indicates data not available.

SOURCE: The Monitoring the Future Study, the University of Michigan.

^aAnswer alternatives were: (1) Probably impossible, (2) Very difficult, (3) Fairly difficult, (4) Fairly easy, (5) Very easy. For 8th and 10th grades, there was another category—"Can't say, drug unfamiliar"—which was included in the calculation of these percentages.

^b8th and 10th grade only: 1993 data from one questionnaire form only. N is one-half of N indicated.

Monitoring the Future

across these grade levels: the children in lower grades are considerably less likely to have friends who use, and thus, are less likely to have access through those friends. The differences between age groups may also reflect less willingness and/or less motivation on the part of those who deal drugs to establish contact with younger children.

- **Marijuana** appears to be universally available to high school seniors; some 83% report that they think it would be "very easy" or "fairly easy" for them to get—more than double the number who report ever having used it (35%).
- After marijuana, twelfth grade students indicate that **amphetamines** are among the easiest drugs to obtain (62%).
- Nearly half of the seniors (49%) now see **cocaine** and **LSD** as readily available to them; about 45% of all seniors think **cocaine powder**, **crack**, **barbiturates**, and **steroids** are readily available.
- **Tranquilizers**, **opiates other than heroin**, **heroin**, **psychedelics other than LSD**, and **PCP** are reported as available by substantial minorities of seniors (41%, 38%, 34%, 34%, and 32%, respectively). See Table 30 for the full list of drugs included in the questions for twelfth graders; a few of these were not asked of the younger students.
- Even drugs such as **ice**, **ecstasy**, and the **nitrite inhalants** are seen as available by about a quarter of the seniors.
- Among seniors, the great majority of fairly recent users of **all drugs**—that is, of those who have illicitly used the drug in the past year—feel that it would be easy for them to get that same type of drug (usually two-thirds or more). (Data are not displayed here.)

Trends in Perceived Availability for Twelfth Graders

Trend data on availability for seniors are presented in Figures 33a through 33c and in Table 30.

- For the first time since the study began in 1975, **marijuana** showed a small but statistically significant decline in perceived availability between 1982 and 1984 (down 4 percentage points to 85%), undoubtedly due to the reduced proportion of seniors who had friends who used. There has been little further change since then, and 83% of the class of 1993 think marijuana would be easy to get.

TABLE 30

FIGURE 33a

Trends in Perceived Availability of Drugs for Twelfth Graders

FIGURE 33b

Trends in Perceived Availability of Drugs for Twelfth Graders

FIGURE 33c

Trends in Perceived Availability of Drugs for Twelfth Graders

- **Amphetamines** showed a jump in availability of 11 percentage points between 1979 and 1982 (to 71%); but availability dropped by 14 percentage points between 1982 and 1991 (to 57%). Since 1991 there has once again been an increase in use to 62% in 1993.
- The perceived availability of **barbiturates** also jumped about 6% between 1980 and 1982, but dropped back by 11 points in subsequent years reflecting its continued drop in the number of users.
- Between 1977 and 1980—the period of increased use—there was a substantial increase (15 percentage points) in the perceived availability of **cocaine** (see Figures 33a and 33b and Table 30). Among recent cocaine users there also was a substantial increase observed over that three-year interval (data not shown). Availability then leveled, and dropped some in 1983 and 1984, before rising significantly (by 4%) in 1985, again as use rose. Perceived availability rose another 2.6% in 1986. Since 1986 actual use of cocaine has dropped sharply, *but* reported availability continued to rise through 1989. The fact that there was no drop in perceived availability between 1986 and 1989 leads us to discount any reduction in supply as a possible explanation for the significant decline in use observed in those years. Between 1989 and 1993 there was a significant 10-percentage-point decrease in perceived availability—perhaps reflecting the impact of the greatly reduced proportion of seniors who have friends who use (which dropped by 13 percentage points in the same interval).
- **Crack** availability has only been asked since 1987; it has fluctuated between 40% and 47% (Figure 33a).
- The use of **tranquilizers** declined fairly steadily between 1977 and 1992, and perceived availability declined over the same period, though by a smaller proportion. After 1992 availability has stayed level at 41%.
- The perceived availability of **LSD** dropped sharply between 1975 and 1986, from 46% to 29% saying the drug would be "fairly easy" or "very easy" to get. Since then availability rose to 41% in 1990, where it remained in 1991. In 1992 availability increased sharply to 46%, and in 1993 it increased significantly again to 49%, its highest point since the study began. (See Table 30.)
- The availability of **other psychedelics** dropped sharply between 1975 and 1978. Since 1978 the use of **PCP** dropped substantially, although availability has risen slightly in recent years, increasing significantly in 1992 and 1993.

Monitoring the Future

- For the decade between 1976 and 1986 there was little change in the perceived availability of **heroin** (Figure 33b). A significant increase occurred between 1986 and 1989 followed by very little change in 1990 and 1991. In 1992, perceived availability again increased significantly. It is now perceived as being fairly easy or very easy to get by fully one-third (34%) of the twelfth graders. The 1992 and 1993 figures are the highest attained since the study began.
- **Other opiates** have shown a very slight, gradual, upward shift in availability, from 29% in 1980 to 38% in 1989, with little change since.
- When the sample is restricted to recent users of each of the drugs, who might be assumed to be the most knowledgeable about actual availability on the street, all these trends in perceived availability are similar (data not shown).

Trends in Perceived Availability for Eighth and Tenth Graders

Because comparable questions on availability have only been asked of eighth and tenth graders since 1992, little trend information is available as yet.

- Eighth graders showed no significant change in perceived availability of the illicit drugs (Table 29), but the tenth graders did show significant increases for **marijuana** and **amphetamines**. The increases may well reflect an increase in the proportions of tenth graders having friends who use. Tenth graders also showed some decline in the availability of **ice**.
- There was no significant change in the very high level of availability of **cigarettes** to tenth graders (89% say they would be "fairly easy" or "very easy" to get). Eighth graders (three-quarters say cigarettes would be "fairly easy" or "very easy" to get) showed a significant decline in availability, perhaps reflecting the effects of some state-level programs.
- There was no significant change in the very high level of **alcohol** availability for tenth graders (83%). However, for eighth graders, perceived availability dropped significantly here, as well, to 74%.

The Importance of Supply Reduction vs. Demand Reduction

- Overall, it is important to note that **supply reduction** does not appear to have played a major role in perhaps the two most important downturns in use which have occurred to date—namely, those for **marijuana** and **cocaine**. (See Figures 23 and 24.) In the case of cocaine, perceived availability was actually rising during much of the period of downturn in use—a conclusion which is corroborated by data from the Drug Enforcement Administration on trends in the price and purity of cocaine on the streets. In the case of marijuana, availability

has remained almost universal to this age group over the last 18 years, while use has dropped substantially until this year. Similarly, *amphetamine* use has declined appreciably since 1981 with only a modest corresponding change in perceived availability. Finally, *heroin* use has not risen among seniors even though there has been a substantial increase in availability.

- What *has* changed dramatically are young peoples' beliefs about the dangers of using *marijuana* and *cocaine*; and, as we have been saying for some years, we believe these changes have led to a decrease in use directly through their impact on the young peoples' demand for these drugs, and indirectly through their impact on personal disapproval and subsequently on peer norms. Because the perceived risk of *amphetamine* use was not changing much when amphetamine use was declining substantially (1981-1986), other factors must help to account for the decline in demand for that class of drugs—quite conceivably a displacement to cocaine. And because the three classes of drugs (marijuana, cocaine and amphetamines) have shown *different* patterns of change, it is highly unlikely that a general factor (e.g., a general shift against drug use) can explain their various trends.

The turnaround in *marijuana* use among twelfth graders in 1993 adds more compelling evidence to this interpretation. It was neither preceded, nor accompanied, by any increase in perceived availability, but it was *both* preceded, and accompanied, by a decrease in perceived risk. Peer disapproval dropped sharply in 1993, a year *after* perceived risk began to change, consistent with our interpretation that perceived risk can be an important determinant of disapproval.

Chapter 10

OTHER FINDINGS FROM THE STUDY

Each year this section presents additional recent findings from the Monitoring the Future study. Sometimes these have been published recently as journal articles or chapters; however, the first two analyses included here—on the use of nonprescription stimulants and daily marijuana use—have not been reported elsewhere.

THE USE OF NONPRESCRIPTION STIMULANTS

As is discussed in other chapters of this report, between 1979 and 1981 we observed a substantial increase in reported stimulant use by high school students. We had reason to believe that a fair part of that increase was attributable to nonprescription stimulants of two general types—"look-alike" drugs (pseudo-amphetamines, usually sold by mail order, which look like, and often have names that sound like, real amphetamines) and over-the-counter stimulants (primarily diet pills and stay-awake pills). These drugs usually contain caffeine, ephedrine, and/or phenylpropanolamine as their active ingredients.

Beginning with the 1982 survey we introduced new questions on some questionnaire forms in order to more accurately assess the use of amphetamines as well as to assess the use of the "look-alikes," diet pills, and stay-awake pills of the nonprescription variety. For example, on one of the five questionnaire forms in 1982-1988 and on one of six questionnaire forms beginning in 1989, respondents were asked to indicate on how many occasions (if any) they had taken nonprescription diet pills such as Dietac™, Dexatrim™, and Prolamine™ (a) in their lifetime, (b) in the prior twelve months, and (c) in the prior thirty days. (These correspond to the standard usage questions asked for all drugs.) Similar questions were asked about nonprescription stay-awake pills (such as No-Doz™, Vivarin™, Wake™, and Caffedrine™) and the "look-alike" stimulants. (The latter were described at some length in the actual question.)

On three of the five questionnaire forms in 1982 and 1983 (and in all questionnaire forms thereafter) respondents were also asked about their use of prescription amphetamines, with very explicit instructions to exclude the use of over-the-counter and "look-alike" drugs.

Prevalence of Use in 1992 Among Seniors

- Tables 31a, 31b, and 31c give the prevalence levels for these various classes of stimulants. As can be seen, a substantial proportion of students (15%) have used over-the-counter *diet pills* and 4% have used them in just the past month. Some 0.3% of seniors are using them daily.
- Based on the data presented earlier in this report, we know that very similar proportions are using actual *amphetamines*, 15% lifetime, 4% monthly, and 0.2% daily prevalence.

- Fewer students knowingly use the **look-alikes** than use diet pills or amphetamines (adjusted): 11% lifetime, 3% monthly, and 0.3% daily prevalence. Of course, it is probable that some proportion of those who think they are getting real amphetamines have actually been sold look-alikes, which are far cheaper for drug dealers to purchase.
- Currently, **stay-awake pills** are the most widely used stimulant: 31% lifetime, 7% monthly, and 0.4% daily prevalence.
- In 1983 the newly revised question on amphetamine use yielded prevalence estimates which were about one-quarter to one-third lower than the original version of the question, indicating that some distortion in the unadjusted estimates was occurring as a result of the inclusion of some nonprescription stimulant use. We believe that there should be little or no such distortion in recent years primarily due to the improvement in the questions but also to the fact that has been a considerable decline in the use of diet pills and look-alikes, as discussed below.

Subgroup Differences

- Figure 34 shows the prevalence figures for these drug classes for **males and females** separately. It can be seen that the use of **diet pills** is dramatically higher among females than among males. In fact, the absolute prevalence levels for females are impressively high, 23% report some experience with them and 5%—or one in every twenty females—report use in just the last month. For all other stimulants the prevalence rates for both sexes are fairly close.
- A similar comparison for those planning four years of college (referred to here as the "college-bound") and those who are not, has shown some differences as well (data not shown). This year's results show no difference between these two groups in their use of **stay-awake pills**; annual prevalence is 19% for both college-bound and noncollege-bound. Use of **diet pills** is slightly higher for the noncollege-bound: annual prevalence is 10% vs. 7% for the college-bound. Use of the **look-alikes** is also slightly higher among the noncollege-bound (8% vs. 6%).
- There have not been any dramatic **regional differences** in the use of diet pills, but the 1991-1993 data show slightly higher rates for "look-alikes" and stay-awake pills in the North Central region.
- All three nonprescription stimulants have lowest prevalence in the large cities.
- The use of all of the nonprescription stimulants (i.e., **diet pills, stay-awake pills, and "look-alikes"**) is substantially higher among those who have had experience with the use of illicit drugs than among

FIGURE 34

**Prevalence and Recency of Use, by Sex
Amphetamines and Non-Prescription Stimulants
Twelfth Graders, 1993**

those who have not, and highest among those who have become most involved with illicit drugs (see Table 32). For example, only 4% of those who have abstained from any illicit drug use report ever having used a *look-alike* stimulant, compared to 8% of those who report having used only marijuana and 30% of those who report having used some illicit drug other than marijuana.

Trends in Use Among Seniors

- Because these questions were new in 1982, trends can be assessed directly only since then. However, it is worth noting that the adjusted 1982 figures for *amphetamines* are higher than the unadjusted figures for all years prior to 1980. (See Tables 11 through 14.) This suggests that there was indeed an increase in amphetamine use between 1979 and 1982—or at least an increase in what, to the best of the respondent's knowledge, were amphetamines.
- During the 1980s there were increased legislative and law enforcement efforts to curb the manufacture and distribution of *look-alike pills*. Perhaps as a result, the use of these pills decreased from 1982 to 1992; for example, annual prevalence went from 10.8% in 1982 to 5.7% in 1988. Most of the decline occurred among those who have had experience with illicit drugs other than marijuana—the group primarily involved in the use of "look-alikes". Since 1988 use has remained essentially level.
- Use of *diet pills* decreased between 1983 and 1993. Over that interval annual prevalence fell from 21% to 8%. Nearly all of this decline occurred among the group who had used illicit drugs other than marijuana.
- The use of *stay-awake pills* increased significantly in the early to mid-1980s; annual prevalence increased from 12% in 1982 to 26% in 1988. Since then it has dropped back somewhat, to 19% in 1993. Both the increase and decrease occurred primarily among those who have had experience in the use of illicit drugs, including those who had used only marijuana (data not shown).
- All subgroups (defined by sex, college plans, region of the country, and population size) showed similarly large increases from 1982 to 1988 in their use of *stay-awake pills*. All subgroups decreased in annual prevalence between 1988 and 1992, though there has been rather little decrease in the North Central region.
- Subgroup differences in trends for *diet pills* and *look-alikes* for the most part reflect the overall trends.

^aThis means that, of those who have never used an illicit drug, 8.8 percent have used a diet pill at least once.

THE USE OF MARIJUANA ON A DAILY BASIS

In past reports in this series, we summarized a number of findings regarding daily marijuana users, including what kind of people they are, how use changes after high school for different subgroups, and what daily users see to be the negative consequences of their use.³⁸ In 1982 a special question segment was introduced into the study in one of the five questionnaire forms in order to secure more detailed measurement of individual patterns of daily use. (This question was included in one of six forms since 1988.) More specifically, respondents were asked (a) whether at any time during their lives they had ever used marijuana on a daily or near-daily basis for at least a month and, if so, (b) how recently they had done that, (c) when they first had done it, and (d) how many total months they had smoked marijuana daily, cumulating over their whole lifetime. The results of our analyses of these questions follow.

Lifetime Prevalence of Daily Use

- **Current daily use**, defined as use on twenty or more occasions in the past thirty days, fluctuates widely since the study began, as we know from the trend data presented earlier in this report. It rose from 6.0% among seniors in 1975 to 10.7% in 1978, declined to 1.9% by 1992, then began to increase again in 1993, to 2.4%.
- Since 1982, we have found the **lifetime prevalence of daily use** for a month or more to be far higher than current daily use—e.g., at 9.6% or one in every ten seniors in 1993 vs. 2.4% for current daily use. In other words, the proportion who describe themselves as having been daily or near-daily users at some time in their lives is four times as high as the number who describe themselves as current daily users. (However, we believe it very likely that this ratio has changed dramatically over the life of the study as a result of the large secular trends in daily use. Therefore, it would be inaccurate to extrapolate to the class of 1978, for example, and deduce that their lifetime prevalence of daily use was four times their 10.7% current use figure that year. An investigation of data from a follow-up panel of the class of 1978 confirms this assertion.)
- Utilizing data collected in 1989 from follow-up panels from the earlier graduating classes of 1976 through 1988, we found that the lifetime prevalence of daily marijuana use for these graduates (ranging in age from about 19 to 31) was 20%. Approximately one-fourth of the older portion of that group—graduates from the classes of 1976 through 1979—indicated having been daily marijuana users for a month or more at some time in their lives.

³⁸For the original reports see the following, which are available from the author: Johnston, L.D. (1981). Frequent marijuana use: Correlates, possible effects, and reasons for using and quitting. In R. DeSilva, R. Dupont, & G. Russell (Eds.), *Treating the marijuana dependent person*. New York: The American Council on Marijuana. Also see Johnston, L.D. (1982). A review and analysis of recent changes in marijuana use by American young people. In *Marijuana: The national impact on education*, New York: The American Council on Marijuana.

Monitoring the Future

Grade of First Daily Use

- Of those 1993 seniors who were daily users at some time (9.6% of the sample), over half (53%, or 5.1% of all seniors) began that pattern of use before tenth grade. However, the secular trends in daily use must be recalled. Active daily use reached its peak among seniors in 1978, when the 1990 graduating class was in kindergarten. Thus we are confident that different graduating classes show different age-associated patterns of onset.
- A high proportion of all who were to become daily users by the end of high school had done so by the end of grade ten (71% of the eventual daily users). The percentages of all seniors who started daily marijuana use in each grade level is presented in Table 33.

Recency of Daily Use

- About two-thirds (69%) of those who report ever having been daily marijuana users (for at least a one-month interval) have smoked that frequently in the past year, while about one-third (31%) of them say they last used that frequently "about two years ago" or longer. On the other hand, 38% of all such users (or 2.6% of the entire sample) classified themselves as having used daily or almost daily in the past month (the period for which we define *current daily users*). Our own operational definition of current daily users yields 2.4% in 1993, very close to the 2.6% defined by the respondents themselves.

Duration of Daily Use

- It seems likely that the most serious long-term health consequences associated with marijuana use will be directly related to the duration of heavy use and in the late 1970's there was considerable concern that a large population of chronic heavy users would evolve. Thus a question was introduced which asks the respondent to estimate the *cumulative* number of months he or she has smoked marijuana daily or nearly daily. While hardly an adequate measure of the many different possible cross-time patterns of use—a number of which may eventually prove to be important to distinguish—it does provide a gross measure of the total length of exposure to heavy use.
- Table 33 gives the distribution of answers to this question. It shows that nearly two-thirds (63%) of those seniors with daily use experience have used "about one year" or less cumulatively—at least by the end of twelfth grade. In fact, less than a third (29%) have used less than three months cumulatively. On the other hand, nearly one-third (31%, or 2.9% of *all* seniors) have used marijuana daily "about two years" or more cumulatively.

Subgroup Differences

- There is now only a modest *sex difference* in the proportion having ever been a daily user—10.7% for males and 7.2% for females; but the cumulative duration of daily use is now somewhat longer for the males.
- Whether or not the student has *college plans* is strongly related to lifetime prevalence of daily marijuana use, as well as to current prevalence. Of those planning four years of college, 7.7% had used daily compared with 11.6% of those without such plans. And the college-bound users show a distinctly shorter cumulative duration of use, with a lower proportion of them still using daily. Among those in each group who did use daily, the age-at-onset pattern is younger for the noncollege-bound.
- At present there are fair sized *regional differences* in lifetime prevalence of daily use; the Northeast is highest, with 12.0% having used daily at some time, the West is next at 10.4%, followed by the North Central at 9.3%, and the South at 8.3%.
- The differences associated with *urbanicity* are now fairly small as is true for current daily use. Lifetime prevalence of daily marijuana use is 8.4% in the large cities, 8.9% in the smaller cities, and 7.6% in the nonurban areas. Current daily use is 1.9% in the large cities, 1.7% in the smaller cities, and 2.1% in the nonurban areas.

Trends in Use of Marijuana on a Daily Basis

- Table 34 presents trend data on the lifetime prevalence of daily use for a month or more. It shows a decline since 1982 when this measure was first used, through 1992—from 21% to 8%. In 1993, it rose to 10%.
- Between 1982 and 1992, the decline in lifetime daily use was slightly stronger among males (20% to 8%) than among females (from 18% to 8%); and the absolute drop was larger in the noncollege-bound group (23% to 11%) than among the college-bound (14% to 6%), although the proportional drop was not. In the 1993 turnaround, most of the increase appeared to occur among the males (+2.4%) and the college-bound (+1.8%), though these differences are not statistically significant.
- Lifetime prevalence of daily use dropped in all four regions of the country after 1982. The decline was greatest in the Northeast, which had the highest rate in 1986.
- All three population density levels have shown declines in lifetime daily use.

- Daily use prior to tenth grade has declined from 13% in the class of 1982 to 5% in the class of 1993. (This corresponds to people who were ninth graders between 1979 to 1989.) Subgroup trends may be examined in Table 34.

HIGH SCHOOL EDUCATIONAL SUCCESS AS A LONG-TERM DETERRENT OF SUBSTANCE ABUSE³⁹

Evidence drawn from decades of research indicates that educational commitment and success in school are negatively related to substance use and other problem behaviors prior to and during high school. But what happens after high school? In an article published this past year in the *Journal of Health and Social Behavior*, we reported the outcome of analyses we conducted to address two related questions: 1) Does educational success in high school continue to have a negative influence on substance use during the transition to young adulthood, and 2) if so, what are the underlying causal mechanisms?

By following individuals over the course of the transition to young adulthood, we were able to consider three general competing hypotheses regarding the link between high school educational success and subsequent substance use: a *selection hypothesis* (i.e., subsequent substance use is due to pre-existing individual differences in high school educational success, regardless of post-high school experiences), a *socialization hypothesis* (i.e., subsequent substance use is due to post-high school roles and experiences, regardless of high school educational success), or a *differential-socialization hypothesis* (i.e., subsequent substance use is due to differential post-high school socialization experiences that vary according to pre-existing individual differences in high school).

High school educational success was represented by both high school grade point average (GPA) and college plans, and substance use was considered in terms of current cigarette, alcohol, and illicit drug use. We considered post-high school roles and experiences that clearly reflect the major changes and transitions that can occur during young adulthood, including college student status, marital status, living arrangements, and unemployment. Gender and religiosity were included as background characteristics (parental education, number of parents present in the home, urbanicity, and cohort were deleted based on initial analyses). Truancy and the frequency of going out at night for fun and recreation were considered as potential lifestyle mediators of the relationship between educational success and substance use.

Our initial questions did not yield straightforward answers; rather, the answers depended on how educational success was defined and the type of drug considered. Although high school GPA and college plans were highly interrelated, we were able to identify distinctions between them in their impact on subsequent substance use, both in the strength and direction of the overall impact and in the underlying causal mechanism. Neither GPA nor college plans had a direct effect on post-high school substance use, and neither influenced

³⁹Adapted from Schulenberg, J., Bachman, J.G., O'Malley, P.M., & Johnston, L.D. (1994). High school educational success and subsequent substance use: A panel analysis following adolescents into young adulthood. *Journal of Health and Social Behavior*, 35, 45-62.

post-high school drug use via the impact of senior year drug use on post-high school roles and experiences.

High School GPA. Consistent with the selection hypothesis, the negative indirect effect of high school GPA on young adult cigarette, alcohol, and illicit drug use was found to operate almost entirely through the impact of high school GPA on senior year drug use and the stability of drug use over time. This suggests that the long-term effect of high school GPA was due to enduring individual differences that operate regardless of post-high school roles and experiences (after controlling for college plans). Of course, the effect of high school GPA on senior year substance use was only moderate in magnitude, less powerful than other variables more proximal to substance use, and the impact faded a bit over the course of three or four years. Nevertheless, it remains true that in comparison to their age-mates, those who received relatively good grades in high school continued to be less frequent users of alcohol, illicit drugs, and especially cigarettes during the transition to young adulthood. This is of particular importance, given that of all the periods in the life course, the transition to young adulthood is when the use of drugs, particularly alcohol, is most common.

The predominance of the selection effect indicates that the pivotal relationship between high school GPA and senior year substance use is an explanatory factor in the continued negative effect on substance use during young adulthood. Although this relationship is due in part to conventionality (i.e., GPA was positively related to religiosity and negatively related to evenings out and truancy), our findings suggest that there is something extra about getting good grades—above and beyond conventionality—that serves to deter drug use. One possibility is that getting good grades engenders a sense of competence or feelings of control over one's present and future, and that such feelings may have a long-term protective quality.

College Plans During High School. Consistent with the selection hypothesis, the indirect effect of college plans on subsequent cigarette use operated similarly to the indirect effect of GPA. In contrast, and consistent with the differential-socialization hypothesis, college plans were found to have a relatively substantial *positive* indirect effect on young adult alcohol use via college student status and marital status. College plans had no significant net effect on young adult illicit drug use. College plans, of course, lead to college attendance and remaining single between the ages of 18 and 22, and our findings suggest that the college context engenders socialization experiences that promote increases in alcohol use but not cigarette or illicit drug use. As previous findings for the study indicate, these substance use patterns associated with college attendance are likely due to the accompanying living arrangements and lifestyles.

Efforts to increase the educational involvement and success of young people prior to and during high school are likely to have important additional payoffs in terms of reduced substance use that may extend well into adulthood. In contrast, although college plans may shield individuals from drug use during high school, this shield appears to wear thin quickly as they make the transition to young adulthood. During this time, college students, who in high school had been at comparatively low risk for substance use, quickly surpass their non-college age-mates in alcohol use. Our findings underscore the fact that many students experience these norms and opportunities for excessive drinking for the first time when they attend college, thus increasing the potential for the emergence of difficulties directly and indirectly related to alcohol use.

OTHER DATA ON CORRELATES AND TRENDS

Hundreds of correlates of drug use, without accompanying interpretation, may be found in the series of annual volumes from the study entitled *Monitoring the Future: Questionnaire Responses from the Nation's High School Seniors*.⁴⁰ For each year since 1975, a separate hardbound volume presents univariate and selected bivariate distributions on all questions contained in the study. A host of variables dealing explicitly with drugs—many of them not covered here—are contained in that series. Bivariate tables are provided for *all* questions each year distributed against an index of lifetime illicit drug involvement, making it possible to examine the relationship between hundreds of potential "risk factors" and drug use.

A special cross-time reference index is contained in each volume to facilitate locating the same question across different years. One can thus derive *trend* data on some 1500 to 2000 variables for the entire sample or for important subgroups (based on sex, race, region, college plans, and drug involvement).

⁴⁰This series is available from the Monitoring the Future Project, Institute for Social Research, The University of Michigan, Ann Arbor, Michigan 48109.

Appendix 1

PREVALENCE AND TREND ESTIMATES ADJUSTED FOR ABSENTEES AND DROPOUTS

One question which has arisen over the years in regard to this study has concerned the degree to which the prevalence and trend estimates derived from twelfth graders are an accurate reflection of the reality which pertains to all young people who would be in the same class or age cohort, including those who have dropped out of school by senior year. In 1985 we published an extensive chapter on this topic in a volume in the NIDA Research Monograph series.⁴¹ We will attempt in this Appendix to summarize the main points relevant to this issue of sample coverage.

First, it should be noted that two segments of the entire class/age cohort are missing from the data collected each year from seniors: those who are still enrolled in school but who are absent the day of data collection (the "absentees") and those who will not graduate from high school (the dropouts). The absentees constitute virtually all of the nonrespondents shown in the response rate given in Table 2 in Chapter 3 of this volume (since refusal rates are negligible) or about 18% of all seniors (or 15% of the class/age cohort). Based on our review of available Census data, dropouts account for approximately 15% of the class/age cohort.

The methods we used to estimate the prevalence rates for these two missing segments are summarized briefly here. Then, the effects of adding in these two segments to the calculation of the overall prevalence rates for two drug classes are presented along with the impact on the trend estimates. Two illicit drugs have been chosen for illustrative purposes: marijuana, the most prevalent of the illicit drugs, and cocaine, one of the more dangerous and less prevalent drugs. Estimates for high school seniors are presented for both lifetime and 30-day prevalence for each drug.

CORRECTIONS FOR LOWER GRADE LEVELS

Before estimates of corrections for seniors are discussed, it should be noted that the twelfth grade represents the "worst case" of underestimations. Rates of dropping out and absenteeism are lower for the other two grades, eighth and tenth. With respect to dropping out, only a very few members of an age cohort have ceased attending school by grade eight, when most are age 13 or 14. Most tenth graders are age 15 or 16, and Census data indicate that only a small proportion (less than 5%) would have dropped out by then.⁴² Thus, any

⁴¹Johnston, L.D., & O'Malley, P.M. (1985). Issues of validity and population coverage in student surveys of drug use. In B.A. Rouse, N.J. Casual, & L.G. Richards (Eds.), *Self-report methods of estimating drug use: Meeting current challenges to validity* (NIDA Research Monograph No. 57 (ADM) 85-1402). Washington, DC: U.S. Government Printing Office.

⁴²According to the *Statistical Abstract of the United States 1992*, the proportion of the civilian non-institutionalized population of the United States enrolled in school is 99.7% among 7-13 year olds and 98.8% among 14-15 year olds. It drops to 93.3% for 16-17 year olds combined, but there is probably a considerable difference between age 16 and age 17. Eighth graders in the spring of the school year are mostly (and about equally) 13-14 years old; while tenth graders are mostly (and about equally) 15 and 16 years old. These data, then, would suggest that dropouts are no more than 0.8% of eighth graders and 4.0% of tenth graders. U.S. Department of Commerce. (1992). *Statistical Abstract of the United States 1992: The National Data Book*. (112th Ed.) Washington, D.C.: Bureau of the Census. (p. 143)

Monitoring the Future

correction for the missing dropouts should be negligible at eighth grade, and quite small at tenth grade.

Regarding absentees, Table 2, presented earlier, shows that while absentees comprise 16% of the seniors who should be in school, they comprise only 12% of tenth graders and 10% of eighth graders. Thus, the change in prevalence estimates which would result from corrections for this missing segment also would be considerably less than for twelfth graders.

In sum, the modest corrections which will result from the corrections for dropouts and absentees at the twelfth grade level set outside limits for what would be found at eighth and tenth grade; in fact, it is clear that the corrections would be considerably smaller at tenth grade and far smaller at eighth grade. Since the corrections described for twelfth graders turn out to be modest ones, we have not undertaken comparable corrections for eighth and tenth graders.

THE EFFECTS OF MISSING ABSENTEES

To be able to assess the effects of excluding absentees on the estimates of twelfth grade drug use, we included a question in the study which asks students how many days of school they had missed in the previous four weeks. Using this variable, we can place individuals into different strata as a function of how often they tend to be absent. For example, all students who had been absent 50% of the time could form one stratum. Assuming that absence on the day of the administration is a fairly random event, we can use the respondents in this stratum to represent all students in their stratum, including the ones who happen to be absent that particular day. By giving them a double weight, they can be used to represent both themselves and the other 50% of their stratum who were absent that day. Those who say they were in school only one-third of the time would get a weight of three to represent themselves plus the two-thirds in their stratum who were not there, and so forth. Using this method, we found that absentees as a group have appreciably higher than average usage levels for all licit and illicit drugs. However, looking at 1983 data, we found that their omission did not depress any of the prevalence estimates in any of the drugs by more than 2.7 percentage points, due to the fact that they represent such a small proportion of the total target sample. Considering that a substantial proportion of those who are absent likely are absent for reasons unrelated to drug use—such as illness and participation in extracurricular activities—it may be surprising to see even these differences. In any case, from the point of view of instruction policy or public perceptions, the small "corrections" would appear to be of little or no significance. (The correction in 1983 across all 13 drugs in lifetime prevalence averaged only 1.4 percentage points.) Further, such corrections should have virtually no effect on cross-time trend estimates unless the rate of absenteeism was changing appreciably; and we find no evidence in our data that it has. Put another way, the presence of a slight underestimate which is constant across time should not influence trend results. Should absentee rates start changing, then it might be argued that such corrections should be presented routinely.

THE EFFECTS OF MISSING DROPOUTS

Unfortunately, we cannot derive corrections from data gathered from seniors to impute directly the prevalence rates for dropouts, as we did for absentees, since we have no completely appropriate stratum from which we have "sampled". We believe, based on our own previous research, as well as the work of others, that dropouts generally have prevalence rates for all classes of drugs substantially higher than the in-school students. In fact, the dropouts may be fairly similar to the absentees.

We have consistently estimated the proportion who fail to complete high school to be approximately 15%; Figure A-1 displays the completion rate for the years 1972 through 1993 based on Census data. As the figure indicates, completion rates (and the complement, dropout rates) have been quite constant over this interval for persons 20-24 years old.⁴³ (Younger age brackets are more difficult to use because they include some young people who are still enrolled in high school.) Monitoring the Future probably covers some small proportion of the 15%, since the survey of seniors takes place a few months before graduation, and not everyone will graduate. On the other hand, perhaps 1% to 2% of the age group which Census shows as having a diploma get it through a General Equivalency Degree and thus would not be covered in Monitoring the Future. (Elliott and Voss report this result for less than 2% of their sample in their follow-up study of 2617 ninth graders in California who were followed through their high school years.⁴⁴) So these two factors probably cancel each other out. Thus, we use 15% as our estimate of the proportion of a class cohort not covered.

Extrapolating to dropouts from absentees. To estimate the drug usage prevalence rates for this group we have used two quite different approaches. The first was based on extrapolations from seniors participating in this study. Using this method we developed estimates under three different assumptions: that the difference between dropouts and the participating seniors in the study was equivalent to (a) the difference between absentees and the participating seniors, (b) one and one-half times that difference, and (c) twice that difference. The last assumption we would consider a rather extreme one.

The second general method involved using the best national data currently available on drug use among dropouts—namely the National Household Surveys on Drug Abuse (NHSDA).⁴⁵ While these surveys have rather small samples of dropouts in the relevant age range in any given year, they should at least provide unbiased estimates for dropouts still in the household population.

Using the first assumption—that dropouts are just like absentees—we found that no prevalence rate was changed by more than 5% over the estimate based on 1983 seniors only, even with the simultaneous correction for both absentees and dropouts. (The method for

calculating prevalence rates for the absentees is the one described in the previous section.) The largest correction in 1983 involved marijuana, with lifetime prevalence rising from just under 60% to 64%. Even under the most extreme assumption—which results in exceptionally high prevalence rates for dropouts on all drugs, for example 90% lifetime prevalence for marijuana—the overall correction in any of the prevalence figures for any drug remained less than 7.5%. Again, marijuana showed the biggest correction (7.5% in annual prevalence, raising it from 46% uncorrected to 54% with corrections for both absentees and dropouts). As we would have expected, the biggest *proportional* change occurred for heroin, since it represents the most deviant end of the drug-using spectrum and thus usually would be most associated with truancy and dropping out.

Extrapolating from the household surveys. The second method of estimating drug use among dropouts was by comparing the household survey data on dropouts with the data from those remaining in school. We originally conducted secondary analyses of the archived data from the 1977 and 1979 National Household Surveys (NHSDA). Analyses using more current NHSDA data are shown in the next section. Analyses were restricted to the age range 17 to 19 years old, since about 95% of the Monitoring the Future seniors fall in this range. Of course, the numbers of cases are small. In the 1977 survey there were only 46 dropouts and 175 enrolled seniors in this age group. In the 1979 survey 92 dropouts and 266 seniors were included.

For marijuana, the estimated differences from the household survey data came out at a level which was at or below the least extreme assumption made in the previous method (where dropouts are assumed to have the same drug use levels as absentees). While this may have been comforting to the authors of the present report, we must admit that we believe these household samples underrepresented the more drug-prone dropouts to some degree. Thus we concluded that estimates closer to those made under the second assumption in the previous method may be closer to reality—that is, that dropouts are likely to deviate from participating seniors by one and one-half times the amount that absentees deviate from them.

We should note that there are a number of reasons for dropping out, many of which bear no relationship to drug use, including economic hardship in the family and certain learning disabilities and health problems. At the national level, the extreme groups such as those in jail or without a permanent place of residence are undoubtedly very small as a proportion of the total age groups and probably even as a proportion of all dropouts. Thus, regardless of their prevalence rates, they would be unable to move the prevalence estimates by a very large proportion except in the case of the most rare events—in particular, heroin use. We do believe that in the case of heroin use—particularly regular use—we are very likely unable to get a very accurate estimate even with the corrections used in this report. The same may be true for crack cocaine and PCP. For the remaining drugs, we conclude that our estimates based on participating seniors, though somewhat low, are not bad approximations for the age group as a whole.

Effects of omitting dropouts in trend estimates. Whether the omission of dropouts affects the estimates of trends in prevalence rates is a separate question, however, from the degree to which it affects absolute estimates at a given point in time. The relevant issues parallel those discussed earlier regarding the possible effects on trends of omitting the absentees. Most important is the question of whether the rate of dropping out has been changing in the

Monitoring the Future

country, since a substantial change would mean that seniors studied in different years would represent noncomparable segments of the whole class/age cohort. Fortunately for the purposes of this study, at least, the official government data provided in Figure A-1 indicate a very stable rate of dropping out since 1972.

Given that there appears to be no sound evidence of a change in the dropout rate, the only reason that trend data from seniors would deviate from trends for the entire class cohort (including dropouts) would be if the constant proportion who have been dropping out showed trends contrary to those observed among seniors; and even then, because of their small numbers, they would have to show dramatically different trends to be able to change the trend story very much for the age group as a whole. There has been no hypothesis offered for such a differential shift among dropouts which these authors, at least, find very convincing.

One hypothesis occasionally heard was that more youngsters were being expelled from school, or voluntarily leaving school, because of their drug use; and that this explained the downturn in the use of many drugs being reported by the study in the 1980s. However, it is hard to reconcile this hypothesis with the virtually flat dropout rates over the period displayed in Figure A-1, unless one posits a perfectly offsetting tendency for more completion among those who are less drug prone—hardly a very parsimonious explanation. Further, the reported prevalence of some drugs remained remarkably stable throughout those years of the study (e.g., alcohol and opiates other than heroin) and the prevalence of some rose (cocaine until 1987, and amphetamines until 1981). These facts are not very consistent with the hypothesis that there had been an increased rate of departure by the most drug prone. Certainly more youngsters leaving school in the 1980s have drug problems than was true in the 1960s. (So do more of those who stay in.) However, they still seem likely to be very much the same segment of the population, given the degree of association that exists between drug use and deviance and problem behaviors of various sorts.

MORE RECENT UPDATE ON CORRECTIONS FOR DROPOUTS

Recently, we have looked at some additional data regarding the effects of exclusion of dropouts. One additional source of information is a special report from the 1988 National Household Survey on Drug Abuse.⁴⁶ This report compared selected drug use rates for 16-17 year old respondents who were classified as currently enrolled in school or as having dropped out of school. The authors of that report concluded that: "The percentage of youth aged 16 and 17 who reported use of any illicit drug, marijuana, cocaine, and alcohol did not differ significantly among dropouts and those currently enrolled in school." (page 22) Differences in illicit drug use between high school graduates and dropouts were also slight among 21- to 25-year olds.

⁴⁶National Institute on Drug Abuse. (1991). "Drug use among youth: Findings from the 1988 National Household Survey on Drug Abuse." DHHS Publication No. (ADM) 91-1765. Rockville MD: Author.

The authors noted that their findings appeared somewhat contrary to popular conceptions, as well as to some other research. Moreover, they reported that preliminary data for 20- to 34-year olds from the 1990 NHSDA showed higher rates of cocaine and marijuana use among dropouts. The authors conjectured that perhaps differences between dropouts and graduates emerge after age 25, when more young adults have finished college. They also noted that other variables, such as race, ethnicity, and socioeconomic status may confound the dropout versus graduate comparison. An additional problem was that, prior to the 1991 survey, the NHSDA did not include individuals who did not live in households; perhaps the more deviant dropouts were overrepresented in the excluded groups.

More recently, we have examined some data from the 1991 National Household Surveys on Drug Abuse. Specifically, we obtained estimated prevalence rates for two key illicit drugs, marijuana and cocaine, among dropouts ages 16-18. Table A-1 indicates the lifetime and monthly prevalences for Monitoring the Future seniors, and for NHSDA seniors and NHSDA dropouts.

Table A-1. Comparison of 1991 Monitoring the Future Seniors, NHSDA Seniors, and NHSDA Dropouts

	MTF Seniors	NHSDA Seniors	NHSDA Dropouts 16-18
Marijuana			
Life	36.7	31.9	60.7
30Days	13.8	11.6	21.0
Cocaine			
Life	7.8	8.6	20.0
30Days	1.4	1.3	2.3

As can be seen, the 1991 NHSDA dropouts aged 16-18 were distinctly higher in cocaine and marijuana use than the NHSDA seniors, and the 1991 MTF seniors. (This result is somewhat contradictory to the results from the earlier report based on 1988 data. The relatively small numbers of dropouts make definitive statements difficult.) As discussed above, however, the relatively small proportion of the population who are dropouts reduces the impact that their higher prevalences have on overall population estimates.

Table A-2 compares the total population prevalence estimates derived using two different methods. The first method shows the estimates that result when we use the method we previously described, which provided the data shown in Figure A-2, where the prevalence

Table A-2. Estimated Prevalence Rates for Marijuana and Cocaine, 1991, Based on Monitoring the Future and National Household Survey on Drug Abuse

Monitoring the Future						NHSDA			Combined	
	Seniors Present	Seniors Absent	Dropouts	Seniors Absent & Present	Total	Seniors	Dropouts (Age 16-18)	Difference	Dropouts	Total
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
Cocaine- 30 Day	1.4	2.7	3.3	1.6	1.9	1.3	2.3	1.0	2.6	1.8
Cocaine-Life	7.8	15.3	19.1	9.0	10.3	8.6	20.0	11.4	20.4	10.7
Marijuana- 30 Day	13.8	22.0	26.1	15.1	16.7	11.6	21.0	9.4	24.5	16.5
Marijuana-Life	36.7	49.9	56.5	38.8	41.4	31.9	60.7	28.8	67.6	43.1

NOTES: The entries in columns are as follows:

- (2) estimates based on all MTF seniors who completed questionnaires.
- (3) estimated prevalences among seniors who were absent (using data from seniors who were present, as explained in text).
- (4) estimated prevalences among dropouts, based on assumptions described in text.
- (5) estimated prevalences among seniors present plus seniors who were absent.
- (6) estimated prevalences among seniors present, seniors who were absent, and same-age dropouts.
- (7) estimates based on all NHSDA respondents who were high school seniors.
- (8) estimates based on all NHSDA respondents, 16-18 years old, who were not attending school and had not graduated.
- (9) difference between columns (7) and (8), that is, the difference between all NHSDA seniors and dropouts; this is considered a valid estimate of the population difference between seniors and dropouts.
- (10) sum of columns (5) and (9), combining MTF estimated use among all seniors (present and absent) plus the estimated population difference between all seniors and dropouts, resulting in an estimated prevalence among dropouts.
- (11) weighted combined estimate of prevalence, using MTF estimates for all seniors (column (5)), and estimate of prevalence among dropouts (column (10)).

rate among dropouts is assumed to be higher than seniors present by 1.5 times the difference between seniors present and seniors absent. Column (3) in Table A-2 is calculated by reweighting the data for absenteeism, and calculating the estimated prevalence among absentees. The prevalence among dropouts is estimated by assuming that they differ from seniors present by a factor 1.5 times greater than the difference between seniors present and seniors absent (column (4)). The data in columns (2) and (3) are combined in appropriate proportion to derive estimated prevalence among seniors, present plus absentees (column (5)). The data in columns (2), (3), and (4) are combined in appropriate proportion to derive estimated prevalence among seniors present, seniors absent, plus dropouts; these estimates are shown in column (6). (For 1991, the percentage of dropouts is estimated at 15% and the percentage of seniors absent is 15.9% [based on data collected in participating schools]; these figures result in the following proportions for the total age cohort: seniors present, .715; seniors absent, .135, and dropouts, .150.)

The second method takes the estimated prevalence from MTF, adjusted for absentee bias, and further adjusts by assuming that the difference between NHSDA seniors versus NHSDA dropouts is the best estimate of the difference between dropouts and stayins (column (11)).

The data in columns (7) and (8) are prevalence rates reported in the 1991 NHSDA seniors and for dropouts age 16-18, and column (9) shows the algebraic difference. This "bias" is assumed to be a valid estimate of the difference between seniors (present plus absent) versus dropouts. This "bias" is then applied to the estimated prevalence based on MTF data of seniors present plus absent to derive an estimate of the prevalence among dropouts (column (10)). These estimates are higher than the NHSDA estimates because MTF estimates for nondropouts are higher than the NHSDA estimates. Finally, the data in columns (5) and (10) are combined in appropriate proportion to derive estimates presented in column (11).

Note that the estimated prevalences among dropouts based on NHSDA data are not very different from the estimates using the "1.5" factor. (Compare columns (10) and (4)). Consequently, the data in column (11) show estimates that are highly similar to those in column (6).

The similarity suggests that the estimates of corrections for dropouts that we have been providing, based on earlier data, are probably still reasonable. In fact, based on all of the NHSDA data, they may actually be conservatively high.

Finally, an additional piece of information relative to the comparison of drug use rates among students who stay in school and dropouts comes from Fagan and Pabon (1990)⁴⁷, who report some comparison data between high school students and dropouts from six inner-city neighborhoods. About 1,000 male students and 1,000 female students were compared with 255 male dropouts and 143 female dropouts. Although dropouts were generally more delinquent, and more involved with substance use, there was also a great deal of variability by specific class of substances. As would be generally expected, marijuana use was lower among students, compared to dropouts. Psychedelic use, on the other hand, was *higher*

⁴⁷Fagan, J. & Pabon, E. (1990). Contributions of delinquency and substance use to school dropout among inner-city youths. *Youth & Society*, 21, 306-354.

Monitoring the Future

among students than among dropouts. Use of tranquilizers and barbiturates was also higher among students. Amphetamine use was lower among male students, but higher among female students, compared to same-sex dropouts. Cocaine use was similar, lower among male students, but higher among female students, compared to dropouts. Students of both genders reported more heroin use than did dropouts. Inhalant use did not differ significantly between students and dropouts.

Overall, the data indicate a distinct variation, depending on the class of drug. Although heroin use was surprisingly higher among students, it should be noted that this study was in a single city, and may not be representative of the broader array of students and dropouts. The study does show, however, that the usual assumption that dropouts invariably use drugs more than students is not always true.

SUMMARY AND CONCLUSIONS

In sum, while we believe there is some underestimation of the prevalence of drug use in the cohort at large as a result of the dropouts being omitted from the universe of the study, we think the degree of underestimation is rather limited for all drugs (with the possible exceptions of heroin, crack, and PCP) and, more importantly, that trend estimates have been rather little affected. Short of having good trend data gathered directly from dropouts—a more expensive and technically difficult research task which we are only now in a position to undertake—we cannot close the case definitively. Nevertheless, we think the available evidence argues strongly against alternative hypotheses—a conclusion which was also reached by the members of the NIDA technical review on this subject held in 1982.⁴⁸

. . . the analyses provided in this report show that failure to include these two groups (absentees and dropouts) does not substantially affect the estimates of the incidence and prevalence of drug use.

EXAMPLES OF REVISED ESTIMATES FOR TWO DRUGS

Figure A-2 provides the prevalence and trend estimates of marijuana and cocaine, for both the lifetime and thirty-day prevalence periods, showing (a) the original estimates based on *participating seniors* only; (b) the empirically derived, revised estimates based on *all seniors*, including the absentees; and (c) estimates for the *entire class/age cohort*. The last estimate was developed using the assumption judged to be most reasonable above—namely that the dropouts differ from participating seniors by one and one-half times the amount that the absentees do. Estimates were calculated separately for each year, thus taking into account any differences from year to year in the participation or absentee rates. The dropout rate was taken as a constant 15% of the age group across all years, based on Census estimates.

FIGURE A-2

Estimates of Prevalence and Trends for the Entire Age/Class Cohort,
Adjusting for Absentees and Dropouts for Twelfth Graders

Monitoring the Future

As Figure A-2 illustrates, any difference in the slopes of the trend lines between the original and revised estimates is extremely, almost infinitesimally, small. The prevalence estimates are higher, of course, but not dramatically so, and certainly not enough to have any serious policy implications. As stated above, the corrections for eighth and tenth grade samples should be considerably less, and there is certainly no reason to think that absentee or dropout rates at those levels have changed since 1991 in any way which could have changed their trend stories. Therefore, we have confidence that the trend stories which have shown up for the in-school populations represented in this study would be very similar to the trend stories which would pertain if the entire age cohorts had been the universes from which we sampled.

Appendix 2

DEFINITIONS OF BACKGROUND AND DEMOGRAPHIC SUBGROUPS

Throughout this volume data are presented for the total sample of eighth, tenth and twelfth graders. Data are also presented for many subgroups of students. The following are brief descriptions of the background and demographic subgroups used in this volume.

- Total:** The total sample of respondents in a given year of the study.
- Sex:** *Male and female.* Respondents with missing data on the question asking the respondent's sex are omitted from both groupings.
- College Plans:** Respondents not answering the college plans question are omitted from both groupings. (Among those who do not expect to complete a four-year college program a number still expect to get some post-secondary education.) College plans groupings are defined as follows:
- None or under 4 years.* Respondents who indicate they "definitely won't" or "probably won't" graduate from a four-year college program.
- Complete 4 years.* Respondents who indicate they "definitely will" or "probably will" graduate from a four-year college program.
- Region:** Region of the country in which the respondent lives. There are four mutually exclusive regions of the country. The regional classifications are based on Census categories which are defined as follows:
- Northeast.* Census classifications of New England and Middle Atlantic states; includes Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania.
- North Central.* Census classifications of East North Central and West North Central states; includes Ohio, Indiana, Illinois, Michigan, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas.

South. Census classifications of South Atlantic, East South Central, and West South Central States; includes Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, Mississippi, Arkansas, Louisiana, Oklahoma, and Texas.

West. Census classifications of Mountain and Pacific states: includes Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Washington, Oregon, and California.

**Population
Density:**

Population density of the area in which the schools are located. There are three mutually exclusive groups which are defined below. (1975-1985 samples are based on the 1970 Census; in 1986 one-half of the sample is based on the 1970 Census, the other half of the sample is based on the 1980 Census; after 1986 the samples are based on the 1980 Census. The three groups are defined in terms of Standard Metropolitan Statistical Area (SMSA) designations through 1985, when we changed to the new Census Bureau classifications of Metropolitan Statistical Areas (MSAs), as is described below:

Large SMSAs. In the 1975-1985 samples these are the twelve largest Standard Metropolitan Statistical Areas (SMSA) as of the 1970 Census: New York, Los Angeles, Chicago, Philadelphia, Detroit, San Francisco, Washington, Boston, Pittsburgh, St. Louis, Baltimore and Cleveland. In samples collected after 1986 the "large SMSA" group consisted of the 16 largest SMSAs as of the 1980 Census. These 16 SMSAs include all of the SMSAs mentioned above (except Cleveland) and the SMSAs of Dallas-Fort Worth, Houston, Nassau-Suffolk, Minneapolis-St. Paul and Atlanta.

Other SMSAs. Includes all other Standard Metropolitan Statistical Areas except those listed above. Except in the New England States, an SMSA is a county or group of contiguous counties which contains at least one city of 50,000 inhabitants or more, or "twin cities" with a combined population of at least 50,000. In the New England States SMSAs consist of towns and cities instead of counties. Each SMSA must include at least one central city, and the complete title of an SMSA identifies the central city or cities. For the complete description of the criteria used in defining MSAs, see the Office of Management and the Budget publication, *Metropolitan Statistical Areas, 1990* (NTIS-PB90-214420), Washington, D.C. The population living in SMSAs is designated as the metropolitan population.

Non-SMSAs. Includes all areas not designated as SMSAs (or MSAs). The population living outside SMSAs constitutes the nonmetropolitan population.

**Parental
Education:**

This is an average of mother's education and father's education reported on the following scale: (1) completed grade school or less, (2) some high school, (3) completed high school, (4) some college, (5) completed college, (6) graduate or professional school after college. Missing data was allowed on one of the two variables.

Race/Ethnicity:

White. Includes those respondents who describe themselves as White or Caucasian.

Black. Includes those respondents who in 1975-1990 describe themselves as Black or Afro-American, or who after 1990 describe themselves as Black or African-American.

Hispanic. Includes those respondents who in 1975-1990 describe themselves as Mexican American or Chicano, or Puerto Rican or other Latin American. After 1990 this group includes those respondents who describe themselves as Mexican American or Chicano, or Cuban American, or Puerto Rican American, or other Latin American.
