## PREFACE

This paper is the twenty-sixth in a series growing out of studies of radar cross sections at The University of Michigan Research Institute. The primary aims of this program are:

1.          To show that radar cross sections can be determined analytically.

2. A.    To obtain means for computing the radiation patterns from antennas by approximate techniques which determine the pattern to the accuracy required in military problems but which do not require the exact solutions.

   B.    To obtain means for computing the radar cross sections of various objects of military interest.

   (Since 2A and 2B are interrelated by the reciprocity theorem it is necessary to solve only one of these problems.)

3.          To demonstrate that these theoretical cross sections and theoretically determined radiation patterns are in agreement with experimentally determined ones.

Intermediate objectives are:

1. A.    To compute the exact theoretical cross sections of various simple bodies by solution of the appropriate boundary-value problems arising from electromagnetic theory.

   B.    Compute the exact radiation patterns from infinitesimal sources on the surfaces of simple shapes by the solution of appropriate boundary-value problems arising from electromagnetic theory.

   (Since 1A and 1B are interrelated by the reciprocity theorem it is necessary to solve only one of these problems.)

2.          To examine the various approximations possible in this problem and to determine the limits of their validity and utility.

3.          To find means of combining the simple-body solutions in order to determine the cross sections of composite bodies.

4.  To tabulate various formulas and functions necessary to enable such computations to be done quickly for arbitrary objects.

5.  To collect, summarize, and evaluate existing experimental data.

K.M. Siegel

## SUMMARY

We present an exposition and certain generalizations of recent work on a class of problems in classical electromagnetic theory. Briefly, we indicate the approach as the Fock theory. It is a method of obtaining the field induced by an incident electromagnetic wave on or near the surface of a good conductor. The surface is restricted to be smooth, convex, and of characteristic dimensions which are "large" with respect to the wavelength of the incident radiation. The term "large" will be made more precise below.

I

## TWO DIMENSIONAL PROBLEMS

At the outset we make the point that Fock's method is an essentially two-dimensional

method which has as its prototype the solution of the diffraction of electromagnetic radiation

by a perfectly conducting, infinite circular cylinder. For this reason we propose to review

the solution of the circular cylinder problem. We follow and add somewhat to the treatment

of W. Franz (Ref. 1). We consider a perfectly conducting circular cylinder of radius  a

having its axis along the Z-axis of a Cartesian coordinate system. Let a plane wave be
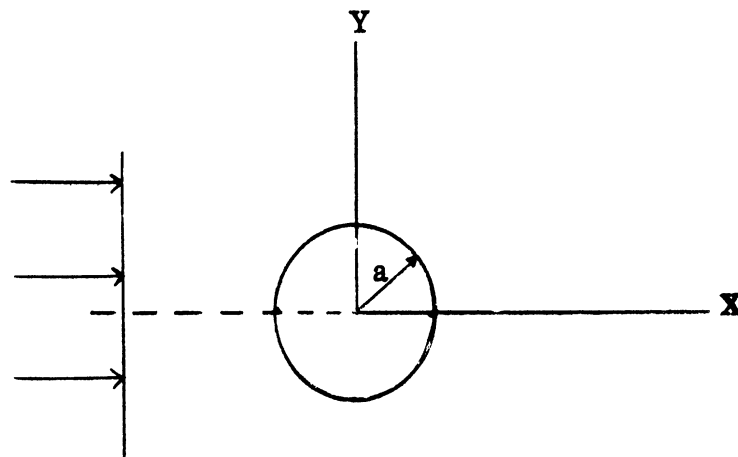

incident along the X-axis .

Figure 1.1

We now wish to determine the magnetic field induced on the surface of the cylinder. If the incident magnetic field is in the Z-direction

$$\vec{H}_0 = e^{ikx} \hat{z} , \tag{1.1}$$

the only non-vanishing component of the field on the surface is in the Z-direction. Hence, we write

$$\vec{H} = \hat{z} \psi . \tag{1.2}$$

The function $\psi$ is then required to satisfy the equation

$$(\nabla^2 + k^2) \psi = 0 , \tag{1.3}$$

where $k = \dfrac{2\pi}{\lambda}$, $\lambda$, the wavelength, and the boundary condition

$$\left. \frac{\partial \psi}{\partial r} \right|_{r=a} = 0 . \tag{1.4}$$

Using a method of R.K. Ritt (Ref. 2) we can immediately write the solution as

$$\psi(a, \phi) = \frac{1}{\pi k a} \int_{-\infty+i\varepsilon}^{\infty+i\varepsilon} d\nu \; \frac{e^{i\nu(\phi - \frac{3\pi}{2})} + e^{-i\nu(\phi - \frac{\pi}{2})}}{\sin \nu \pi \; H_\nu^{(1)'}(ka)} , \tag{1.5}$$

where $\phi$ is the polar angle. But since $\text{Im} \, \nu > 0$ we can make the convergent expansion

$$\frac{1}{\sin \nu \pi} = -2i \, e^{i\nu \pi} \sum_{m=0}^{\infty} e^{2i\nu m\pi} . \tag{1.6}$$

Substituting in Equation (1.5)

$$\psi = \frac{2i}{\pi k a} \sum_{m=0}^{\infty} \int \frac{d\nu}{H_\nu^{(1)'}(ka)} \left[ e^{i\nu(\theta + 2\pi m)} + e^{i\nu(\theta' + 2\pi m)} \right] , \tag{1.7}$$

where we have put

$$\theta = \phi - \frac{\pi}{2} \ ,$$

$$\theta' = \frac{3\pi}{2} - \phi \ . \tag{1.8}$$

So, quite generally, we have the problem of solving integrals of the form

$$I(\Theta) = \int_{-\infty}^{\infty} d\nu \ \frac{e^{i\nu\theta}}{H_{\nu}^{(1)'}(ka)} \ , \tag{1.9}$$

where $\theta$ lies in the range $\left[ -\frac{\pi}{2} , \ \infty \right]$ .

We assume ka $\gg$ 1 and propose to use certain asymptotic approximations to the

Hankel function. The appropriate asymptotic forms are found by an examination of the

stationary points of the phase of the integrand.

Using Langer's uniform asymptotic form of the Hankel function (Ref. 3)

$$H_{\nu}^{(1)}(ka) = e^{i\frac{\pi}{6}} \ \sqrt{\frac{\sin\alpha - \cos\alpha}{\sin\alpha}} \ H_{\frac{1}{3}}^{(1)} \left[ ka \ (\sin\alpha - \alpha \cos\alpha) \right] , \tag{1.10}$$

where $\nu = ka \cos\alpha$. We find that the integrand has the phase

$$\phi = \nu \theta - ka \ (\sin\alpha - \alpha \cos\alpha) \ . \tag{1.11}$$

Hence, the phase is stationary at $\alpha = -\theta$ or

$$\nu = ka \cos\theta \ . \tag{1.12}$$

We now draw a distinction between the regions $\theta \sim -\frac{\pi}{2}$ and $\theta$ near zero or positive.

The first region corresponds to the physical region of direct illumination, geometrical optics

region, and by carrying out a stationary phase (Ref. 4) evaluation of the integral we find

$$I(\theta) \approx \pi\, ka\, e^{ika\, \sin\theta} \ . \tag{1.13}$$

So for $\theta \sim -\frac{\pi}{2}$

$$\psi = 2\, e^{ika\, \cos\phi} \ . \tag{1.14}$$

This is just the geometrical optics approximation. The magnetic field induced on the surface is given approximately by twice the tangential component of the incident magnetic field.

For $\theta$ near zero we have the condition at the stationary phase point that $\nu \sim ka$ and the Langer form reduces to the Nicholson asymptotic form (Ref. 3) which we write as (Ref. 5)

$$H_\nu^{(1)}(ka) = \frac{-1}{\sqrt{\pi}}\, \left(\frac{ka}{2}\right)^{-\frac{1}{3}}\, w(t) \ , \tag{1.15}$$

where

$$t = \left(\frac{ka}{2}\right)^{-\frac{1}{3}}\, (\nu - ka) \ , \tag{1.16}$$

and $w(t)$ is the Airy integral

$$w(t) = \frac{1}{\sqrt{\pi}}\, \int_\Gamma e^{tZ-\frac{1}{3}Z^3}\, dZ \ . \tag{1.17}$$

with the contour $\Gamma$ given in Figure 1.2. Changing the variable of integration to t

$$I(\theta) = -\pi\, i\, m^3\, e^{ika\,\theta}\left\{ \frac{1}{\sqrt{\pi}}\, \int \frac{e^{im\theta t}}{w'(t)}\, dt \right\} \ , \tag{1.18}$$

where $m = \left(\frac{ka}{2}\right)^{\frac{1}{3}}$. The integral to be evaluated is then of the form

$$g(\xi) = \frac{1}{\sqrt{\pi}}\, \int \frac{e^{i\xi t}}{w'(t)}\, dt \ , \tag{1.19}$$

where we restrict $\xi$ to be near zero or positive. For $\xi > 0$ $g(\xi)$ can be given as a residue series

$$g(\xi) = \frac{1}{\sqrt{\pi}} \ (2\pi i) \sum \frac{e^{i\xi t_n}}{\left.\dfrac{\partial w'(t)}{\partial t}\right|_{t=t_n}} \quad , \tag{1.20}$$

where

$$w'(t_n) = 0 \quad , \tag{1.21}$$

and we have deformed the contour to encircle the zero of $w'$ which lies in the first quadrant

(Ref.5). For $\xi \sim 0$, however, the residue series converges slowly for $\xi > 0$ and

diverges for $\xi < 0$, hence $g(\xi)$ need be found by quadratures.

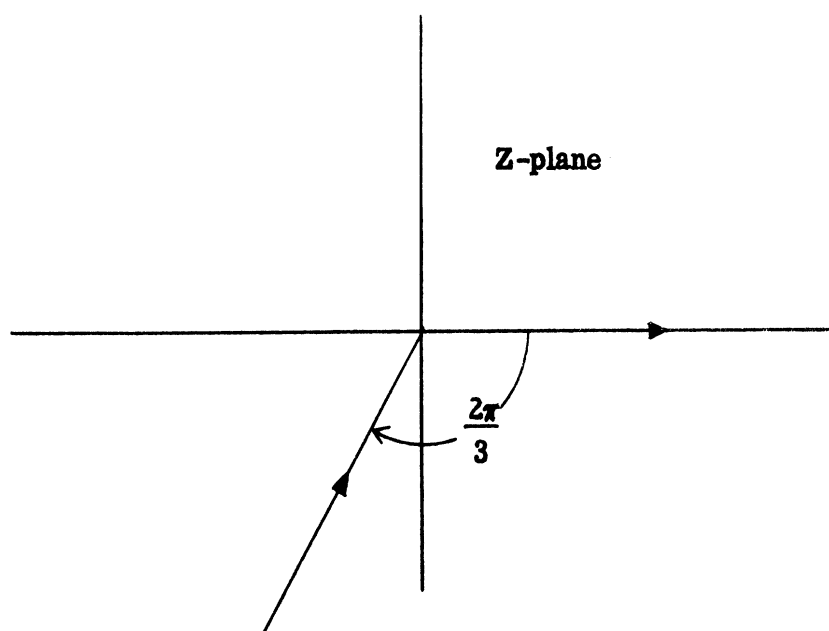

Figure 1.2

The Contour $\Gamma$

Substituting in Equation (1.7)

$$\psi_s = \sum_{n=0}^{\infty} \left\{ e^{ikS_n} g(\xi_n) + e^{ikS'_n} g(\xi'_n) \right\} , \qquad (1.22)$$

where we have put

$$S_n = ka \, (\theta + 2\pi m)$$

$$S_n' = ka \, (\theta' + 2\pi m) , \qquad (1.23)$$

and

$$\xi_n = (\frac{ka}{2})^{\frac{1}{3}} (\theta + 2\pi m)$$

$$\xi_n' = (\frac{ka}{2})^{\frac{1}{3}} (\theta' + 2\pi m) . \qquad (1.24)$$

We anticipate the generalization of this approach and note that $S_m$ and $S_m'$ are path lengths on the cylinder surface while $\xi_m$ and $\xi_m'$ are certain reduced distances corresponding to these path lengths.

Finally we give the interpretation of the terms of Equation (1.22) as "creeping waves". We note that the angles $\theta$ and $\theta'$ measure the angular distance from the geometrical shadow boundaries of cylinder. This is illustrated in Figure 1.3. The interpretation, first proposed by Franz and Deppermann (Ref.6), is that a wave is launched at the shadow boundary and then creeps into the shadow. The subsequent terms in the series with $\theta$ replaced by $\theta + 2\pi n$ will then represent terms which have made n circuits around the cylinder. The justification of this interpretation has been given by Friedlander (Ref.7).
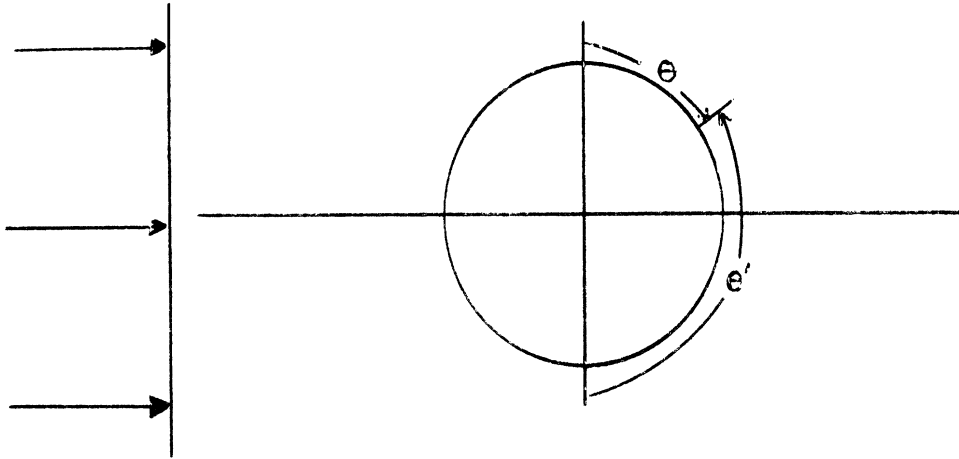

6

**Figure 1.3**

For the incident magnetic field along the y-axis we have an analogous treatment.

Briefly, we have on the surface,

$$\vec{H}_s = \hat{\phi} X \, ,$$  (1.25)

where $\hat{\phi}$ is a unit vector on the surface in the $\phi$ -direction and

$$X = \frac{1}{\pi m^3} \sum \int d\nu \; \frac{e^{i\nu(\theta+2\pi m)} + e^{i\nu(\theta'+2\pi m)}}{H_\nu^{(1)} (ka)} \, .$$  (1.26)

In and near the shadow we approximate the Hankel function by the Airy integral in

Equation (1.26) and find

$$X = \frac{1}{m} \sum_n e^{ikS_n} f(\xi_n) \, ,$$

where $S_n$ and $\xi_n$ are as defined above and

$$f(\xi) = \frac{1}{\sqrt{\pi}} \int \frac{e^{i\xi t}}{w(t)} \, dt \quad . \tag{1.27}$$

Again, $f(\xi)$ can be evaluated by a residue series for $\xi > 0$ and by quadrature for $\xi \sim 0.'$

For $\xi < 0$, the optics region, the Nicholson approximation to the Hankel function

is no longer valid. We use Langer's asymptotic approximation evaluated by stationary

phase and find

$$X \sim 2 \sin \theta \, e^{ikx} \quad , \tag{1.28}$$

The "creeping wave" interpretation obtains just as before.

We now give Fock's work (Ref. 8). Fock, by means of a physical argument gives a

description of the field in the region of the geometric shadow boundary near the surface

in terms of a parabolic differential equation. The import of this in terms of Franz's con-

cept of creeping waves will be made clear below.

We let $f(X, Y) = 0$ be the equation of a convex cylindrical surface, the cylinder axis

in the Z-direction. We consider a plane electromagnetic wave to be incident in the X-

direction and we take the origin of coordinates to be on the surface at the geometrical

shadow boundary, the coordinates given by the solution of $\frac{\partial f}{\partial x} = 0$. This is illustrated in

Figure 1.4. Further, we assume a parabolic approximation to the surface, i.e.

$$f(x,y) = y + \frac{1}{2} \frac{x^2}{R_0} \quad , \tag{1.29}$$

where $R_0$ is the radius of curvature at the shadow boundary, the origin of our coordinate
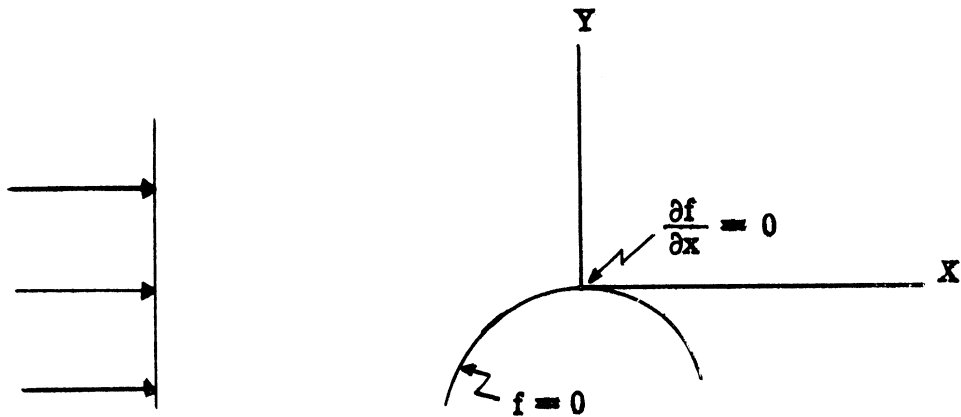

system.

**Figure 1.4**

This essentially two-dimensional vector problem can be characterized in terms of the scalar problems

$$( \nabla^2 + k^2) \psi = 0 , \qquad (1.30)$$

where we assume the time dependence $e^{-ikct}$. The incident wave will have the functional dependence $e^{ikx}$ and this we introduce explicitly putting

$$\psi = e^{ikx} U . \qquad (1.31)$$

Substituting in Equation (1.30) we have

$$U_{xx} + U_{yy} + 2ikU_x = 0 . \qquad (1.32)$$

Now we come to Fock's order argument. He supposes that the variation of the functions U in the y-direction, normal to the surface, is greater than the variation in the x-direction. The physical content of this argument is apparent: There is a large variation

9

in the field quantities on crossing the shadow boundary, $y = 0$, $x > 0$, but having eliminated the dependence on the incident field the variation in the x-direction should be relatively slow.

Fock makes the more precise assumptions

$$\frac{\partial U}{\partial y} = 0 \left( \frac{k}{m} U \right) , \tag{1.33}$$

$$\frac{\partial U}{\partial x} = 0 \left( \frac{k}{M} u \right) , \tag{1.34}$$

where m and M are dimensionless parameters satisfying the inequalities

$$M \gg m \gg 1 . \tag{1.35}$$

Based on this order argument we neglect the second derivative with respect to $x$ in Equation (1.30) and write

$$U_{yy} + 2ikU_x = 0 . \tag{1.36}$$

This implies M is of order $m^2$ so we put

$$M = m^2 , \tag{1.37}$$

and define the new variables

$$\xi = \frac{mx}{R_0} , \tag{1.38}$$

$$\eta = \frac{2m^2}{R_0} \left( y + \frac{1}{2} \frac{x^2}{R_0} \right) . \tag{1.39}$$

Making the change in variables, Equation (1.32) becomes

$$U_{\eta\eta} + i \frac{kR_0}{2} \frac{1}{m^3} \left( U_\xi + \xi U_\eta \right) = 0 . \tag{1.40}$$

10

Now choose m such that the coefficient of the last terms becomes one, i.e. put

$$m^3 = \frac{kR_0}{2} .$$ (1.41)

Equation (1.40) is now

$$U_{\eta\eta} + i(U_\xi + \xi U_\eta) = 0 .$$ (1.42)

For the purposes of a formal simplification we put

$$U = e^{i\frac{\xi^3}{3} - i\xi\eta} V .$$ (1.43)

This results in the equation

$$V_{\eta\eta} + \eta V + i V_\xi = 0 .$$ (1.44)

If the incident magnetic field lies in the Z-direction

$$\vec{H}_0 = e^{ikx} \hat{z} .$$ (1.45)

The total field will be of the form

$$\vec{H} = \psi \hat{z} ,$$

where $\psi$ satisfies Equation (1.3C) and the boundary condition

$$\frac{\partial \psi}{\partial n} \bigg|_{f=0} = 0 ,$$ (1.46)

i.e. the normal derivative of $\psi$ vanishes on the surface. In terms of the function V and

the variables $\xi, \eta$ this condition is

$$\frac{\partial V}{\partial \eta} = 0 \qquad \text{at } \eta = 0 .$$ (1.47)

A particular solution is given by

$$V = e^{i\xi t} w(t-\eta) ,$$ (1.48)

where w(t) is an Airy integral, the solution of

$$w''(t) = t\,w(t) \quad . \tag{1.49}$$

Since two independent solutions are needed we define

$$w_1(t) = \frac{1}{\sqrt{\pi}} \int_{\Gamma_1} e^{Zt - \frac{1}{3}Z^3}\, dZ$$

$$w_2(t) = \frac{1}{\sqrt{\pi}} \int_{\Gamma_2} e^{Zt - \frac{1}{3}Z^3}\, dZ \quad , \tag{1.50}$$

where the contours $\Gamma_1$ and $\Gamma_2$ are given in Figure 1.5. We then look for the solution in

Figure 1.5

the form

$$V = \frac{1}{2\sqrt{\pi}} \int_C e^{i\xi t} \left\{ w_2(t - \xi) - \frac{w_2'(t)}{w_1'(t)}\, w_1(t - \xi) \right\} dt \quad , \tag{1.51}$$

where we note that this satisfies the differential equation and the boundary condition, and

has, from the asymptotic values of the function $w_1$ and $w_2$ the correct phase for this problem.

The contour C is the same as $\Gamma_2'$ in Figure 1.5.

The magnetic field is then

$$H_Z = e^{ikx} \; e^{-i\xi\zeta \; +i\frac{\zeta^3}{3}} \; V \; , \tag{1.52}$$

or making use of the relationship

$$w_1'(t) \, w_2(t) \; - \; w_1(t) \, w_2'(t) \; = \; -2i \; , \tag{1.53}$$

the field on the surface, $\zeta = 0$, is given by

$$H_Z = e^{ikx} \, G(\xi) \; , \tag{1.54}$$

where

$$G(\xi) = e^{i\frac{\xi^3}{3}} \; \frac{1}{\sqrt{\pi}} \; \int_C dt \; \frac{e^{i\xi t}}{w'(t)} \; . \tag{1.55}$$

For the incident field

$$\vec{H}_0 = \hat{y} \, e^{ikx} \; , \tag{1.56}$$

we have the boundary conditions

$$H_Z = 0 \; , \tag{1.57}$$

and since we confine our attention to the region of the shadow boundary, the normal

component of the magnetic field is given by $H_y$

$$H_y = 0 \quad \text{on} \quad S \; . \tag{1.58}$$

Writing as before

$$H_y = e^{ikx} \phi \quad ,$$

$\phi$ must satisfy

$$\nabla^2 \phi + 2ik \frac{\partial \phi}{\partial x} = 0 \quad , \tag{1.59}$$

and

$$\phi = 0 \quad \text{on} \quad S \ .$$

We repeat the order argument and write Equation (1.59) as

$$\frac{\partial^2 \phi}{\partial y^2} + 2ik \frac{\partial \phi}{\partial x} = 0 \tag{1.60}$$

$$\phi = 0 \quad \text{on} \quad S \ .$$

Now $\vec{H}$ is a divergence-free field

$$\nabla \cdot \vec{H} = 0 \quad , \tag{1.61}$$

so if we write

$$\vec{H} = e^{ikx} \vec{H^*} \quad , \tag{1.62}$$

the divergence condition becomes

$$ik H^*_x + \nabla \cdot \vec{H^*} = 0 \ . \tag{1.63}$$

Repeating the order argument we neglect $\dfrac{\partial H^*_x}{\partial x}$ as compared with $ik H^*_x$ leaving

$$H^*_x = \frac{i}{k} \frac{\partial H^*_y}{\partial y} \quad , \tag{1.64}$$

or

$$H^*_x = \frac{i}{m} \frac{\partial \phi}{\partial \eta} \ . \tag{1.65}$$

14

The field component $H_x$ on the surface is given by

$$H_x = e^{ikx} \frac{1}{m} e^{-i\zeta\eta + i\frac{\zeta^3}{3}} \frac{\partial \psi}{\partial \eta} , \qquad (1.66)$$

where $\psi$ satisfies

$$\psi_{\eta\eta} + \eta \psi + i \psi_\zeta = 0$$

$$\psi = 0 \quad \text{on } S . \qquad (1.67)$$

This has a particular solution

$$e^{i\zeta t} w(t-\zeta) . \qquad (1.68)$$

So we write

$$\psi = \frac{1}{2\sqrt{\pi}} \int e^{i\zeta t} \left\{ w_2(t-\eta) - \frac{w_2(t)}{w_1(t)} w_1(t-\eta) \right\} dt , \qquad (1.69)$$

and

$$\left. \frac{\partial \psi}{\partial \eta} \right|_{\eta=0} = \frac{1}{\sqrt{\pi}} \int \frac{e^{i\zeta t}}{w(t)} dt . \qquad (1.70)$$

Using the notation

$$f(\zeta) = \frac{1}{\sqrt{\pi}} \int \frac{e^{i\zeta t}}{w(t)} dt , \qquad (1.71)$$

we have that on the surface

$$H_x = \frac{1}{m} e^{i\frac{\zeta^3}{3}} e^{ikx} f(\zeta) . \qquad (1.72)$$

We are now able to apply Fock's solution to the circular cylinder and compare it with the Franz "creeping wave" solution. From Equations (1.20) and (1.55) we have for the circular cylinder solution and the Fock solution the function

$$g(\xi) = \frac{1}{\sqrt{\pi}} \int \frac{e^{i\xi t}}{w'(t)} \, dt \quad . \tag{1.73}$$

However, we note that for the circular cylinder

$$\xi = \left(\frac{ka}{2}\right)^{\frac{1}{3}} \theta \quad , \tag{1.74}$$

while in the Fock treatment

$$\xi_F = \left(\frac{kR_0}{2}\right)^{\frac{1}{3}} \frac{x}{R_0} \quad , \tag{1.75}$$

or in terms of polar coordinates, since $R_0 = a$ and $x = a \sin \theta$

$$\xi_F = \left(\frac{ka}{2}\right)^{\frac{1}{3}} \sin \theta \quad . \tag{1.76}$$

These arguments of the function $g(\xi)$ thus agree to first order for $\theta \sim 0$. This imposes a restriction on the applicability of Fock's method as it stands.

To bring these solutions into agreement we return to the creeping wave interpretation and Fock's derivation of the parabolic differential equation. From the creeping wave interpretation we have a wave launched at the boundary which then creeps along the surface into the shadow boundary. Now the natural description of such a phenomenon would be by a parabolic differential equation. This Fock has done. However, we note that $\xi_F$ measures distance along the direction of propagation rather than along the surface of the obstacle.

We now observe that the argument used by Fock in his derivation of the parabolic equation is also applicable outside the region $\xi \sim 0$ provided we compare the variations

of field along the surface of the obstacle and perpendicular to the surface of the obstacle.

That is, we can use the Fock equation anywhere in the shadow region provided we define a

new set of variables $\xi$ and $\eta$ for each increment we move into the shadow. To illustrate

this we write the formal solution of Equation (1.44) as

$$V(\xi,\eta) = e^{-iT\xi} V(0,\eta) ,$$

(1.77)

where

$$T = -\left(\frac{\partial^2}{\partial \eta^2} + \eta\right) .$$

This gives us an expression valid for say $\xi \leq \xi_1 << 1$. Given this we then redefine

our variables and write

$$V(\xi,\eta) = e^{-iT(\xi-\xi_1)} V(\xi_1,\xi) ,$$

(1.78)

which generalizes to

$$V(\xi,\eta) = e^{-iT\xi} V(0,\xi) ,$$

(1.79)

with

$$\xi = \int_0^S \left(\frac{kR(s)}{2}\right)^{\frac{1}{3}} \frac{ds}{R(s)} ,$$

(1.80)

where ds is the element of path length along the surface and R(s) is the radius of

curvature at s.

Applying this reasoning to the circular cylinder we have that

$$\xi = \int_0^\theta \left(\frac{ka}{2}\right)^{\frac{1}{3}} \frac{ad\theta}{a}$$

(1.81)

$$= \left(\frac{ka}{2}\right)^{\frac{1}{3}} \theta .$$

(1.82)

This is, however, the expression appearing in Franz's treatment and, hence, we have

brought the Franz and Fock solutions into agreement.

This important generalization of Fock's work was first found by J.B. Keller (Ref. 9).

Keller proceeds from a local solution of the circular cylinder similar to the above treatment.

We now make a comparison of the Fock result for the circular cylinder with the sum

of the harmonic series as given by L. Bailin (Ref. 10) for ka = 12. In this we use two
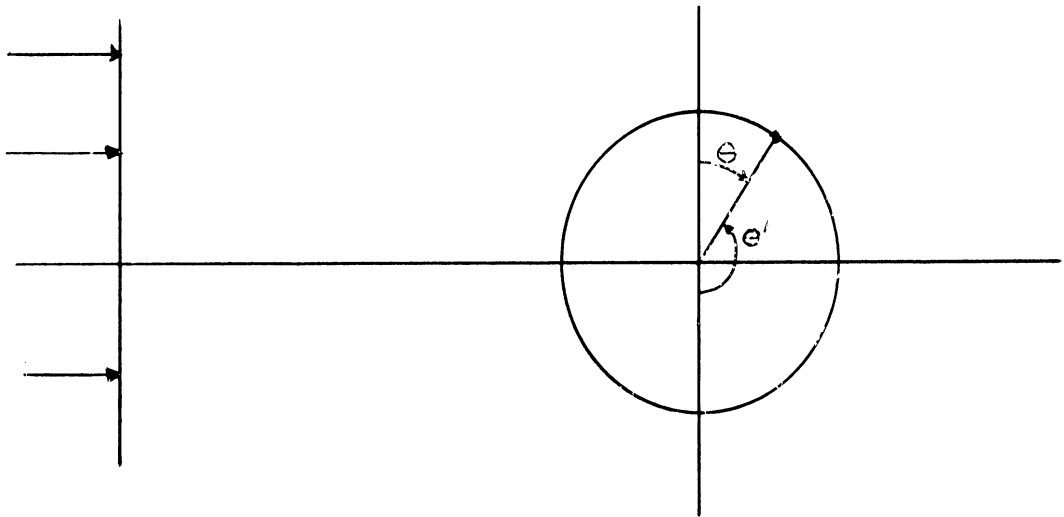

"creeping wave" terms.

Figure 1.6

At the point $\theta$ in Figure 1.6 we determine the contribution arising from the lowest order

terms which "creep" in from each shadow boundary. Then, with the incident magnetic field

parallel to the cylinder axis we have

$$H = e^{ika\,\theta}\, g\!\left[\left(\frac{ka}{2}\right)^{\frac{1}{3}} \theta\right]$$

$$+ e^{ika\,\theta'}\, g\!\left[\left(\frac{ka}{2}\right)^{\frac{1}{3}} \theta'\right] ,$$ (1.83)

where $\theta' = \pi - \theta$. The comparison is shown in Figure 1.7 .

18

Figure 1.7    COMPARISON OF AMPLITUDES FROM EXACT SERIES AND
FOCK'S CURRENT DISTRIBUTION FOR A CIRCULAR CYLINDER WITH ka = 12

As an example of the application of the generalized method we will find the field induced on a perfectly conducting elliptic cylinder by a plane electromagnetic wave. We take the plane wave to be incident along the minor axis of the ellipse with the incident magnetic field parallel to the cylinder axis as in Figure 1.8.

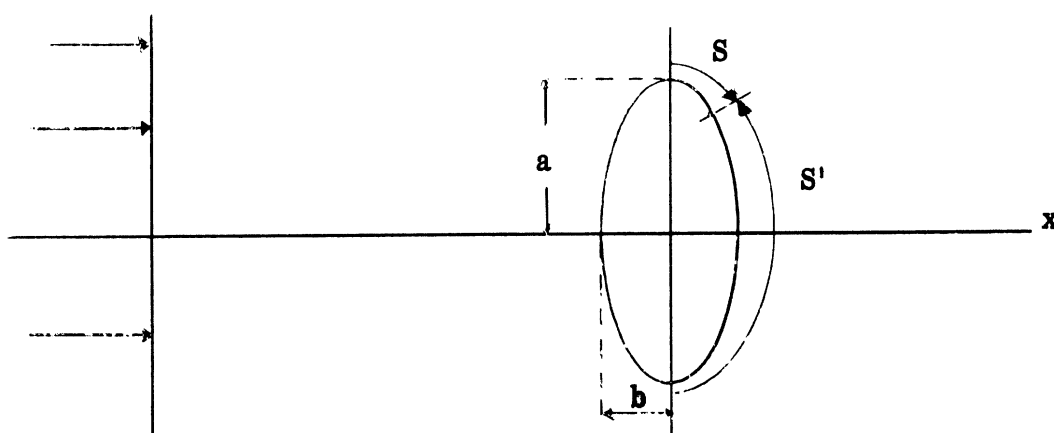

Figure 1.8

If the major and minor semi-axes are a and b respectively the generalized argument of Fock's function is given by

$$\zeta = \int_0^S \left(\frac{kR}{2}\right)^{\frac{1}{3}} \frac{dS}{R}$$

or

$$\zeta = \left(\frac{kb^2}{2a}\right)^{\frac{1}{3}} \left\{ K(\epsilon) - F(\frac{\pi}{2} - \eta, \epsilon) \right\} , \qquad (1.84)$$

and

$$S = a\left[ E(\epsilon) - E(\frac{\pi}{2} - \eta, \epsilon) \right] , \qquad (1.85)$$

where $\mathcal{E}$ is the eccentricity

$$\mathcal{E} = \sqrt{1 - \frac{b^2}{a^2}} \quad , \tag{1.86}$$

the parameter $\eta$ is related to the coordinate by

$$x = b \sin \eta \quad , \tag{1.87}$$

and K and F are elliptic functions of the first kind while E is the elliptic function of the second kind.

$$F(\phi, \mathcal{E}) = \int_0^\phi \frac{d\phi}{\sqrt{1 - \mathcal{E}^2 \sin^2 \phi}} \quad , \tag{1.88}$$

$$F(\frac{\pi}{2}, \mathcal{E}) = K(\mathcal{E}) \quad , \tag{1.89}$$

$$E(\phi, \mathcal{E}) = \int_0^\phi \sqrt{1 - \mathcal{E}^2 \sin^2 \phi} \; d\phi \quad . \tag{1.90}$$

We compute the first two "creeping waves" with

$$S = a(E(\mathcal{E}) - E(\frac{\pi}{2} - \eta, \mathcal{E}))$$

$$S' = a(E(\mathcal{E}) + E(\eta, \mathcal{E})) \quad , \tag{1.91}$$

$$\zeta = \left(\frac{kh^2}{2a}\right)^{\frac{1}{3}} (K(\mathcal{E}) - F(\frac{\pi}{2} - \eta, \mathcal{E}))$$

$$\zeta' = \left(\frac{kb^2}{2a}\right)^{\frac{1}{3}} (K(\mathcal{E}) + F(\eta, \mathcal{E})) \quad . \tag{1.92}$$

These arguments give for the shadow region

$$H_z = e^{ikS} g(\xi) + e^{ikS'} g(\xi') \quad . \tag{1.93}$$

We compare this expression with the experiments of Brick and Wetzel (Ref. 11) for

ka = 12 and kb = 7.5 in Figure 1.9.

Keller (Ref. 12) has given a treatment which makes more precise the content of

Fock's assumptions. This method, "the method of stretching", starts from the reduced

equation,

$$\frac{\partial^2 U}{\partial y^2} + \frac{\partial^2 U}{\partial x^2} + 2ik \frac{\partial U}{\partial x} = 0 \quad . \tag{1.94}$$

We introduce the new variables

$$x' = k^{\alpha} x$$
$$y' = k^{\beta} y \quad , \tag{1.95}$$

so that Equation (1.94) becomes

$$k^{2\alpha} U_{x'x'} + k^{2\beta} U_{y'y'} + 2 ik^{\alpha+1} U_{x'} = 0 \quad . \tag{1.96}$$

Now to impose the condition that this goes to Fock's parabolic equation in the limit

k → ∞ we require

$$2\beta = 1 + \alpha > 2\alpha \geq 0 \quad .$$

This condition results in the equation

$$V_{y'y'} + 2 iV_{x'} = 0 \quad . \tag{1.97}$$

Again taking the surface to be given by

$$y + \frac{1}{2} \frac{x^2}{a} = 0 \quad , \tag{1.98}$$

and imposing the Dirichlet boundary condition in the new variables

Figure 1.9    COMPARISON OF AMPLITUDES FROM EXPERIMENTAL DATA AND FOCK'S
CURRENT DISTRIBUTION FOR AN ELLIPTIC CYLINDER OF ECCENTRICITY 0.780 WITH
ka = 12   AND   kb = 7.5

$$V = 0 \quad \text{on} \quad k^{-\beta} \, y' + k^{-2\alpha} \, \frac{x'^2}{2a} = 0 \ . \tag{1.99}$$

Hence, the boundary condition is satisfied on $y' + \frac{1}{2} \frac{x'^2}{a} = 0$ provided

$$\beta = 2\alpha \ . \tag{1.100}$$

The boundary condition in the limit is then

$$V = 0 \quad \text{on} \quad y' + \frac{1}{2} \frac{x'^2}{a} = 0 \qquad \text{for} \quad k \rightarrow \infty \ . \tag{1.101}$$

Solving for $\alpha$ and $\beta$

$$\alpha = \frac{1}{3} \ , \qquad \beta = \frac{2}{3} \ , \tag{1.102}$$

so the reduced Equation (1.96) becomes

$$U_{y'y'} + 2 \, i \, U_{x'} = k^{-\frac{2}{3}} \, U_{x'x'} \ . \tag{1.103}$$

Since the solutions of Equations (1.104) and (1.97) cannot be the same function we

therefore assume

$$U \sim \sum \frac{U_n}{k^{\lambda n}} \ . \tag{1.104}$$

Substituting (1.104) in (1.103) $U_n$ must satisfy

$$U_{n_{y'y'}} + 2 \, i \, U_{n_{x'}} = - U_{n-1_{x'x'}} \ , \qquad n > 1 \ , \tag{1.105}$$

$$U_{0_{y'y'}} + 2 \, i \, U_{0_{x'}} = 0 \ ,$$

and the boundary condition

$$U_n = 0 \quad \text{on} \quad y' + \frac{1}{2} \frac{x'^2}{a} = 0 \ . \tag{1.106}$$

This treatment is, in itself, no greater justification for the Fock method but it does make more precise the meaning of Fock's essentially physically based assumption.

# II

## THREE DIMENSIONAL PROBLEMS

We now turn to the application of Fock's method to three-dimensional problems.

There is an essential complication present in the case of finite, convex, three-dimensional surfaces. Again we will illustrate the general problem by a prototype problem, scalar scattering by a sphere.

We start with the Dirichlet boundary condition, i.e. we wish the solution of

$$(\nabla^2 + k^2) \psi = 0 \tag{2.1}$$

$$\psi(a) = 0 \tag{2.2}$$

where a is the radius of the sphere. In particular we want to determine

$$\frac{\partial \psi}{\partial r}\bigg|_{r=a} . \tag{2.3}$$

Let the incident field approach along the polar axis then the normal derivative of the field induced on the surface of a sphere of radius a is given by the series

$$\frac{\partial \psi_0}{\partial n} = \sum (n + \frac{1}{2}) \, P_n(\cos \theta) \, e^{-i \frac{\pi}{2} n} \, \frac{1}{\zeta_n^{(1)}(ka)} . \tag{2.4}$$

Since the summand has no singularities with respect to the index on the positive real axis this can be written as the contour integral

$$\frac{\partial \psi_0}{\partial n} = \ldots \int_C \nu \, e^{-i \frac{\pi}{2}} \, \frac{1}{\zeta_{\nu-\frac{1}{2}}^{(1)}(ka)} \, \text{Sec} \, \nu \pi \, P_{\nu-\frac{1}{2}}^*(\cos \theta) \, d\nu \tag{2.5}$$

where C is a contour encircling the positive real axis and where we use the notation

$$P^*_\nu (x) = P_\nu (-x) .\qquad(2.6)$$

Since the integrand is an odd function of $\nu$ regular in the second and fourth quadrants, and having simple poles (the zeros of $\zeta^{(1)}_{-\frac{1}{2}}$ (ka) in the first quadrant) we change the contour C to $C_1$

$\nu$ - plane

$C_1$

C
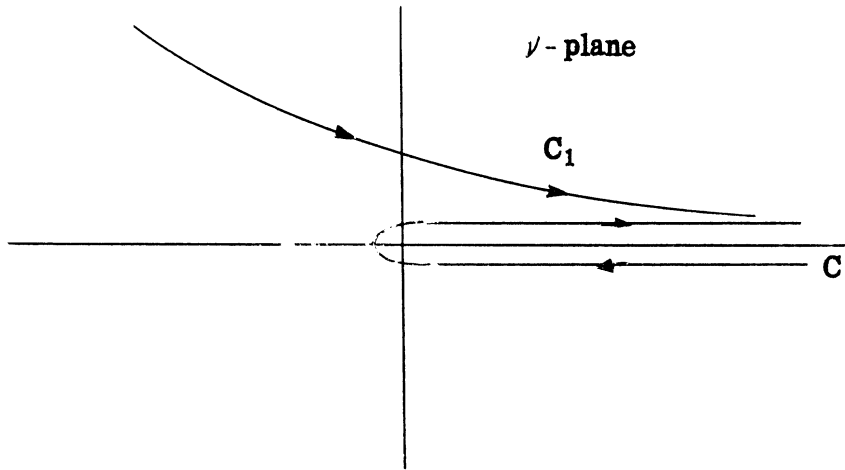

Figure 2.1

Since Im $\nu > 0$ along $C_1$ we make the convergent expansion

$$\text{Sec } \nu\pi = e^{i\pi\nu} \sum_{n=0}^{\infty} e^{2\pi i \nu n} (-)^n .\qquad(2.7)$$

Now making use of the reduction of the Legendre function (Appendix I) we have

$$\text{Sec } \nu\pi \, P^*_{\nu-\frac{1}{2}} (\cos \theta) = e^{i\frac{\pi}{2}} \sum (-)^n \left\{ P^{(+)}_{\nu-\frac{1}{2}} (\theta + 2\pi n) - P^{(+)}_{\nu-\frac{1}{2}} (2\pi(n+1) - \theta) \right\} .$$

$$(2.8)$$

Substituting in the integrand,

27

$$I(\theta) = e^{i\frac{\pi}{2}} \sum (-)^n \left\{ \int_{C_1} e^{-i\frac{\pi}{2}\nu} \frac{1}{\zeta^{(1)}_{\nu-\frac{1}{2}}(ka)} P^{(+)}_{\nu-\frac{1}{2}}(\theta + 2\pi n) \right. -$$

$$\left. - \int_{C_1} e^{-i\frac{\pi}{2}\nu} \frac{1}{\zeta^{(1)}_{\nu-\frac{1}{2}}(ka)} P^{(+)}_{\nu-\frac{1}{2}}(2\pi(n+1) - \theta) \right\} \qquad (2.9)$$

$$I(\theta) = e^{i\frac{\pi}{2}} \sum (-)^n \left\{ I_1(\theta + 2\pi n) - I_1(2\pi(n+1) - \theta) \right\} \qquad (2.10)$$

where

$$I_1(\theta) = \int_{C_1} d\nu \frac{e^{-i\frac{\pi}{2}\nu}}{\zeta^{(1)}_{\nu-\frac{1}{2}}(ka)} P^{(+)}_{\nu-\frac{1}{2}}(\theta) \qquad . \qquad (2.11)$$

For the range $\frac{\pi}{6} < \theta < \frac{5\pi}{6}$ we use the expansion

$$P^{(+)}_{\nu-\frac{1}{2}}(\theta) = \frac{1}{\sqrt{2\pi i \sin\theta}} \frac{\Gamma(\nu+\frac{1}{2})}{\Gamma(\nu+1)} e^{i\nu\theta} F\left(\frac{1}{2}, \frac{1}{2}; \nu+1; \frac{e^{i\theta}}{2i\sin\theta}\right) \qquad (2.12)$$

and the notation

$$\phi = \theta - \frac{\pi}{2} \quad , \qquad \phi' = \frac{3\pi}{2} - \theta \qquad (2.13)$$

so that

$$I(\theta) = \frac{e^{i\frac{\pi}{2}}}{\sqrt{2\pi i \sin\theta}} \sum (-)^n \left\{ \int_{C_1} \frac{\nu\Gamma(\nu+\frac{1}{2})}{\Gamma(\nu+1)} \frac{1}{\zeta^{(1)}_{\nu-\frac{1}{2}}(ka)} \left( e^{i\nu(\phi+2\pi n)} F(\frac{1}{2}, \frac{1}{2}; \nu+1; \right. \right.$$

$$\left. \left. \frac{e^{i\phi}}{2\cos\phi}) - i e^{i\nu(\phi'+2\pi n)} F(\frac{1}{2}, \frac{1}{2}; \nu+1; \frac{e^{i\phi'}}{2\cos\phi'}) \right) \right\} \qquad (2.14)$$

28

or defining

$$I_a(\phi) = \int_{C_1} d\nu \; \frac{\Gamma(\nu+\tfrac{1}{2})}{\Gamma(\nu+1)} \; \frac{1}{\zeta^{(1)}_{\nu-\frac{1}{2}}(ka)} \; e^{i\nu\phi} \; F\left(\frac{1}{2},\frac{1}{2}; \nu+1; \frac{e^{i\phi}}{2\cos\phi}\right) \quad (2.15)$$

we have

$$I(\phi) = \frac{e^{i\frac{\pi}{2}}}{\sqrt{2\pi i \sin\theta}} \sum_{n=0}^{\infty} (-)^n \left\{ I_a(\phi + 2\pi n) - i\, I_a(\phi' + 2\pi n) \right\}. \quad (2.16)$$

The terms of this series correspond to the "creeping waves" of Franz. In this sense we note that $\phi$ and $\phi'$ are just the angular distances measured from the shadow boundaries, Figure 2.2.

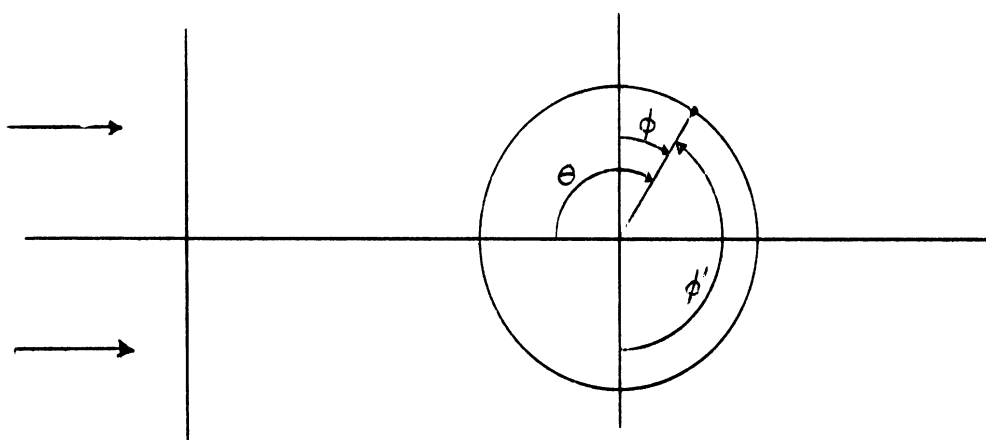

Figure 2.2

The field induced on the surface under the imposition of the Neumann boundary condition follow immediately from the above on the substitution of the derivative of the spherical Hankel function in the denominator of the summand or integrand. We then treat with integrals of the form

$$I_2^1 (\phi) = \int_{C_1} d\nu \; \frac{\nu \; \Gamma(\nu+\frac{1}{2})}{\Gamma(\nu+1)} \; \frac{1}{\zeta^{(1)}_{\nu-\frac{1}{2}} (ka)} \; e^{i\nu\phi} \; F \; . \qquad (2.17)$$

We consider the integrals (2.15) and (2.17) in more detail. Assume a sufficiently

large value of ka so that the Airy integral approximation for the Hankel function and its

derivative is justified. We put e.g.

$$\zeta^{(1)}_{\nu-\frac{1}{2}} (ka) \cong -i \, m^{\frac{1}{2}} \; W(t) \qquad (2.18)$$

where

$$m = \left(\frac{ka}{2}\right)^{\frac{1}{3}} , \qquad t = \frac{\nu - ka}{m} \; . \qquad (2.19)$$

The integral $I_2$ is then essentially of the form

$$I_2 = \int_{C_2} \phi(t) \; \frac{e^{i\zeta t}}{W(t)} \; dt \qquad (2.20)$$

where we put $\zeta = m\phi$ and $C_2$ is the contour running from infinity along arg $t = \frac{2\pi}{3}$ to the

origin and from the origin to infinity along arg $t = 0$.

We note that the form of (2.20) is very like that of Fock's function. In fact, Fock in

his paper, <u>Diffraction of Radio Waves Around the Earth's Surface</u> (Ref. 5) arrives at just

this form which he then approximates by using the asymptotic form

$$\nu \; \frac{\Gamma(\nu + \frac{1}{2})}{\Gamma(\nu+1)} \; F\left(\frac{1}{2}, \frac{1}{2}; \nu +1; \frac{e^{i\theta}}{2i \sin \theta}\right) \sim \sqrt{\nu} \qquad (2.21)$$

Then, in the shadow region, he evaluates (2.20) as a residue series. Since the first pole

occurs near $\nu = ka$, and this for $|ka \sin \theta| >> 1$ is the principal contributor to the

residue series, he approximates (2.21) by $\sqrt{ka}$. What remains is precisely one of Fock's

functions.

Returning to (2.14) we see that there is an essential difference between the sphere

results and the parabolic equation results. The physical significance of this difference is

immediate on noting that the parabolic equation is strictly applicable to a two-dimensional

problem (the infinite circular cylinder) while the sphere being a finite body forces the waves

creeping into the shadow to converge on the pole $\theta = \pi$. This accounts for the term $1/\sqrt{\sin \theta}$

in Equation (2.14). In fact, if we consider that the energy surface density must increase

inversely as the available space we have

$$E \sim |\psi|^2 \sim \frac{1}{\sin \theta} \, , \qquad (2.22)$$

or

$$\psi \sim \frac{1}{\sqrt{\sin \theta}} \, . \qquad (2.23)$$

This result has already been noted by Franz (Ref. 1).

N.A. Logan (Ref. 13) has applied Fock's reasoning in approximating the asymptotic

form of Equation (2.20) itself. Since the major contribution to the integral comes from the

region $t \sim 0$ and $\beta(t)$ is a slowly varying function he writes

31

$$I_2 = \left\{ \int_{C_2} \frac{e^{i\zeta t}}{W(t)} \, dt \right\} \, \phi(0)$$

(2.24)

$$= \frac{ka \, \Gamma(ka + \frac{1}{2})}{\Gamma(ka + 1)} \, F\left( \frac{1}{2}, \frac{1}{2}; \, ka + 1; \, \frac{e^{i\theta}}{2i \sin \theta} \right) \cdot \int_{C_2} \frac{e^{i\zeta t}}{W(t)} \, dt \, ,$$

where he restricts the region of applicability to $|ka \sin \theta| >> 1$.

Near the pole $\theta = \pi$ we use the asymptotic representation,

$$P^*_\nu (\theta) = J_0 \left( (2\nu + 1) \cos \frac{\theta}{2} \right) + O \left( \cos^2 \frac{\theta}{2} \right) \, ,$$

(2.25)

rather than the decomposition into $P_\nu^{(+)}$ and $P_\nu^{(-)}$ which are singular at $\theta = \pi$.

Using the above approximations, N. Logan has made a comparison with the sum of the harmonic series for ka = 20 and has found good agreement between the two. In the transition region between $|\nu \sin \theta| >> 1$ and $|\sin \theta| << 1$ the results from either side are continued into this region and even here the agreement was good.

Fock (Ref. 8) has applied his method to the three-dimensional problem. His result is precisely the same as that presented above for the two-dimensional problem.

We consider a finite, smooth, convex, perfectly conducting body illuminated by a plane electromagnetic wave. We take the plane wave to be incident along the x-direction and erect a coordinate system at some point on the shadow boundary with the y-axis normal to the surface and the z-axis chosen so as to form a right-handed system as in Figure 2.3.
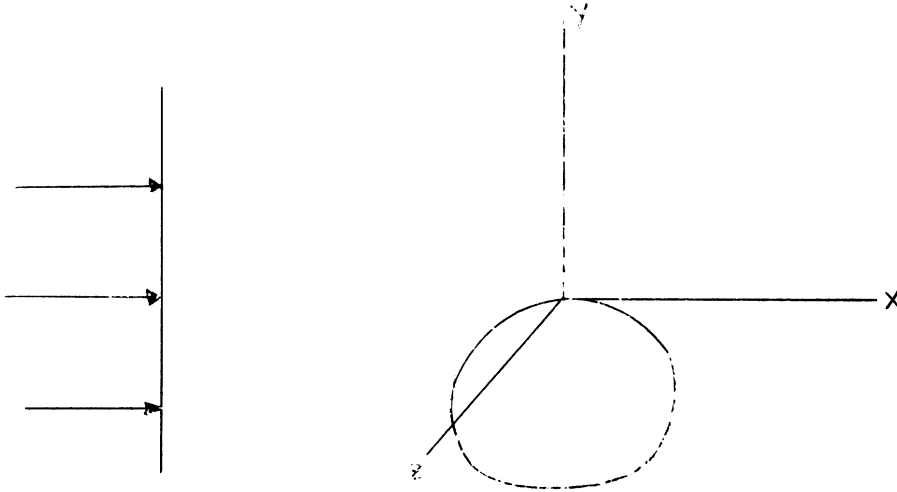

Figure 2.3

As before we perform a local analysis near the origin of the coordinate system. We

write

$$\vec{H} = e^{ikx} \vec{H^*}$$

$$\vec{E} = e^{ikx} \vec{E^*} \quad .$$

(2.26)

Hence, the starred quantities satisfy

$$\nabla x \vec{H^*} + ik\hat{x} \times \vec{H^*} = -ik \vec{E^*}$$

$$\nabla x \vec{E^*} + ik\hat{x} \times \vec{E^*} = ik \vec{H^*} \quad ,$$

(2.27)

from Maxwell's equations for free space.

Now we extend the order argument and write, letting $\psi$ stand for any of the field

components, in Equation (2.27),

$$\frac{\partial \Psi}{\partial y} = O\left(\frac{k}{m}\Psi\right) ,$$

$$\frac{\partial \Psi}{\partial x} = O\left(\frac{k}{M}\Psi\right) ,$$

(2.28)

$$\frac{\partial \Psi}{\partial z} = O\left(\frac{k}{M}\Psi\right) ,$$

where, as before,

$$M \gg m \gg 1 ,$$  (2.29)

and in fact, we put $\qquad M = m^2 .$  (2.30)

Since each of the starred field components must satisfy the reduced wave equation

$$\nabla^2 \Psi + 2ik\frac{\partial \Psi}{\partial x} = 0 ,$$  (2.31)

by applying the ordering assumption of Equation (2.31) we have

$$\frac{\partial^2 \Psi}{\partial y^2} + 2ik\frac{\partial \Psi}{\partial x} = 0 .$$  (2.32)

Finally, dropping the asterisks, we have from the ordering assumptions and

Equation (2.27)

$$E_x = \frac{i}{k}\left(\frac{\partial H_z}{\partial y} - \frac{\partial H_y}{\partial z}\right) ,$$

$$E_y = H_x ,$$

(2.33)

$$E_z = -H_y ,$$

$$H_x = \frac{i}{k}\left(\frac{\partial H_y}{\partial y} + \frac{\partial H_z}{\partial z}\right) .$$

We see then that the three-dimensional solutions of Fock are precisely the two-dimensional solutions given above.

In fact for the incident field

$$\vec{H}_0 = e^{ikx}\, \hat{z} \quad,$$

(2.34)

we put

$$H_x = e^{ikx}\, \psi \quad.$$

(2.35)

Then, near the shadow boundary, $\psi$ must satisfy

$$\frac{\partial^2 \psi}{\partial y^2} + 2\, ik\, \frac{\partial \psi}{\partial x} = 0 \quad,$$

(2.36)

and the boundary condition

$$\frac{\partial \psi}{\partial n}\Bigg|_S = 0 \quad.$$

(2.37)

These are precisely the conditions on $H_z$ in the two-dimensional problem as given above in Equation (1.46).

For the incident field

$$\vec{H}_0 = e^{ikx}\, \hat{y} \quad,$$

(2.38)

on the other hand, we put

$$H_y = e^{ikx}\, \phi \quad,$$

(2.39)

where $\phi$ satisfies

$$\frac{\partial^2 \phi}{\partial y^2} + 2\, ik\, \frac{\partial \phi}{\partial x} = 0 \quad,$$

(2.40)

$$\phi\Bigg|_S = 0 \quad.$$

(2.41)

These are the conditions given in Equation (1.59) for the two-dimensional problem. Again making use of the divergence condition we have

$$H_x = e^{ikx} \frac{1}{k} \frac{\partial \phi}{\partial y} \ . \qquad (2.42)$$

We emphasize that the application of this essentially two-dimensional approach is restricted to the region of the geometric shadow boundary. To carry these solutions farther into the shadow region we must make use of the fact that as the surface area decreases going into the shadow region the energy density must increase. Further, we make the point that the "creeping waves" propagate along geodesics on going into the shadow. The first requirement was illustrated in the treatment of the scalar sphere problem in the appearance of the factor $(\sin \theta)^{-\frac{1}{2}}$ in the expression for the field. The second requirement was met in the tacit assumption that the creeping waves followed great circles on the sphere.

To determine more generally the convergence factor corresponding to $(\sin \theta)^{-\frac{1}{2}}$ in the case of the sphere we consider two adjoining geodesic paths arising on the geometrical shadow boundary. The geodesics are determined by the two conditions:

(1) the point on the shadow boundary at which they arise, and

(2) the angle which the incident radiation makes with the shadow curve.

We write for the two paths

$$\vec{r_1} = \vec{r}(\ell, s_1) \ ,$$

$$\vec{r_2} = \vec{r}(\ell + \Delta \ell \ , s_2) \ , \qquad (2.43)$$

where $\ell$ and $\ell + \Delta\ell$ are points on the shadow boundary and $S_1$ and $S_2$ are path lengths along

the geodesics. This is shown in Figure 2.4.

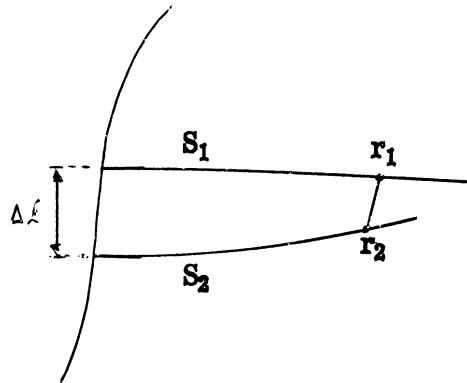

Figure 2.4

We choose $S_1$ and $S_2$ so that $r_1$ and $r_2$ be equiphase points, then the convergence of area

available to the energy propagating into the shadow will be proportional to

$$A = \frac{\vec{r}_1 - \vec{r}_2}{\Delta\ell} \, , \qquad (2.44)$$

or in the limit as $\Delta\ell$ vanishes

$$A(\ell, S) = \left| \frac{d\vec{r}(S, \ell)}{d\ell} \right| . \qquad (2.45)$$

In order to use the Fock method, then, we require the field functions to be

multiplied by the factor $A^{-\frac{1}{2}}$ .

37

III

## AN EXAMPLE ;  THE CONE

As an illustration of the use of Fock's method for something other than a cylinder or sphere, we now propose to determine the field induced on the surface of a perfectly conducting semi-infinite cone by an incident plane electromagnetic wave.  We restrict ourselves to the condition that not all of the cone be illuminated and we shall use Fock's method to find the field on the surface in and near the shadow region.

Here we obtain an approximate method of determining the field on the surface of a perfectly conducting semi-infinite cone which has been illuminated by a plane electromagnetic wave.  In particular we take the direction of incidence to be such that not all of the cone surface is illuminated and find the field on that part of the surface which lies in the shadow and which is far from the tip.  The approach is that of Franz and Fock generalized after an idea of Keller.

We take a plane electromagnetic wave incident on a perfectly conducting semi-infinite cone.  We take the direction of incidence to be such that part of the cone is shadowed and apply the Franz-Fock theory to determine the field induced on the surface of the cone in the shadow and far from the tip.  The term "far from the tip" will be made more precise below and indicated as a requirement for the application of the theory.

Using the coordinate system illustrated in Figure 3.1 the equation of the cone can be given as

Figure 3.1

Coordinate System for the Cone

$$\theta = \theta_0, \qquad \theta_0 > \pi/2 \ . \tag{3.1}$$

The plane wave incident in the xz plane making an angle $\theta(\theta > \pi - \theta_0)$ with the cone axis is again characterized by the unit vector

$$\hat{k} = -\sin\theta\,\hat{i}_x - \cos\theta\,\hat{i}_z \ . \tag{3.2}$$

This fixes the shadow boundaries which are solutions of

$$\hat{k} \cdot \nabla f = 0 \ , \tag{3.3}$$

where f = 0 is the equation of the cone, i.e. in Cartesian coordinates

$$f = x^2 + y^2 - z^2 \tan^2\theta_0 \ . \tag{3.4}$$

Denoting $\emptyset = \pm \emptyset_s$ as the equations of the shadow boundaries we have the solutions of (3.3)

$$\cos\emptyset_s = \frac{\tan\theta_0}{\tan\theta} \ . \tag{3.5}$$

Taking the viewpoint of Franz we consider the field in the shadow as arising from a wave launched at the shadow boundary and propagating along a geodesic according to the prescription of Fock. This makes more precise the condition on the distance from the tip. We now require the radius of curvature everywhere along the geodesic to be much larger than a wavelength. In Fock's notation

$$\left(\frac{kR}{2}\right)^{\frac{1}{3}} \gg 1 \ , \tag{3.6}$$

where R is the radius of curvature and $k = \frac{2\pi}{\lambda}$ with $\lambda$, the wavelength.

Our first step is to find the geodesics, the curvatures, and finally the generalized arguments of Fock's functions.

We need the equation of the geodesic $\vec{r} = \vec{r}\,(\phi)$ which starts at some point $r = r_s$, $\phi = \phi_s$ on the shadow boundary and, at this point, has the unit tangent vector $\hat{T} = \hat{k}$. (In this section r will denote radial distance on the surface, primes denoting differentiation.)

The geodesic is given by the equations

$$\hat{r} \cdot \frac{d^2 \vec{r}}{ds^2} = 0 \qquad\qquad r'' - r \sin^2 \theta_0 \, \phi'^2 = 0$$

$$\text{or} \qquad\qquad\qquad\qquad (3.7)$$

$$\hat{\phi} \cdot \frac{d^2 \vec{r}}{ds^2} = 0 \;, \qquad\qquad r\,\phi'' + 2\,r'\,\phi' = 0 \;,$$

where s is the path length along the geodesic and the primes indicate differentiation with respect to s. From the second of Equations (3.7) we have

$$\frac{\phi''}{\phi'} = -2\,\frac{r'}{r} \;, \qquad\qquad\qquad (3.8)$$

which has the solution

$$\phi' = \frac{\alpha}{r^2} \;, \qquad\qquad\qquad (3.9)$$

where $\alpha$ is to be determined. Now

$$s = \int_{\phi_s}^{\phi} \left[ r^2 \sin^2 \theta_0 + \left(\frac{dr}{d\phi}\right)^2 \right]^{\frac{1}{2}} d\phi \;, \qquad\qquad (3.10)$$

so that

$$\frac{d\phi}{ds} = \phi' = \left[ r^2 \sin^2 \theta_0 + \left(\frac{dr}{d\phi}\right)^2 \right]^{-\frac{1}{2}} \;. \qquad\qquad (3.11)$$

41

Equating this to (3.9) we find

$$\frac{dr}{d\phi} = \frac{r}{\alpha} \sqrt{r^2 - \alpha^2 \sin^2 \theta_0} \quad . \tag{3.12}$$

This has the solution

$$r = \alpha \sin \theta_0 \sec \left[ (\phi - \phi_s) \sin \theta_0 + \psi \right] , \tag{3.13}$$

where $\psi$ is also to be determined.

Applying the condition $r = r_s$ at $\phi = \phi_s$ we have

$$\alpha = r_s \frac{\cos \psi}{\sin \theta_0} \quad . \tag{3.14}$$

The tangent vector is given by

$$\hat{T} = \frac{d\vec{r}}{ds} = \hat{r} \frac{dr}{ds} + r \frac{d\hat{r}}{ds} , \tag{3.15}$$

which, making use of the above, becomes

$$\tag{3.16}$$

$$\hat{T} = \hat{r} \sin \left[ (\phi - \phi_s) \sin \theta_0 + \psi \right] + \hat{\phi} \cos \left[ (\phi - \phi_s) \sin \theta_0 + \psi \right] .$$

Now imposing the condition $\hat{T} = \hat{k}$ at $\phi = \phi_s$, $r = r_s$ we have

$$\sin \psi = -\frac{\cos \theta}{\cos \theta_0} \quad . \tag{3.17}$$

Finally

$$r = r_s \cos \psi \sec \left[ (\phi - \phi_s) \sin \theta_0 + \psi \right]$$

$$\tag{3.18}$$

$$\psi = \sin^{-1} \left\{ -\frac{\cos \theta}{\cos \theta_0} \right\} \quad .$$

The radius of curvature is given by

$$\frac{1}{R} = \left| \frac{d\hat{n}}{ds} \cdot \hat{T} \right| ,$$ (3.19)

where $\hat{n}$ is the unit normal at the point in question. Since $\hat{n} = \hat{\theta}$ ,

$$\frac{d\hat{n}}{ds} = -\frac{\cos \theta_0}{\sin \theta_0} \frac{r_s \cos \psi}{r^2} \hat{\phi} .$$ (3.20)

Thus, using the above expression for $\hat{T}$,

$$\frac{1}{R} = -\frac{r_s^2}{r^3} \cos^2 \psi \cot \theta_0 .$$ (3.21)

We take the generalized argument of the Fock functions in the shadow to be

$$\zeta = \int_0^s \left( \frac{kR}{2} \right)^{\frac{1}{3}} \frac{ds}{R} .$$ (3.22)

Substituting and performing the integration,

$$\zeta = \left( \frac{kr_s}{2} \frac{\cos \psi \sin \theta_0}{\sec^2 \theta_0} \right)^{\frac{1}{3}} (\phi - \phi_s) .$$ (3.23)

Finally we anticipate our need for the path length,

$$s = r \sec \psi \sin \left[ (\phi - \phi_s) \sin \theta_0 \right] .$$ (3.24)

We now apply the Fock theory. We fix on a point $r$, $\phi$ in the shadow and determine the contribution to the field at this point arising from the wave launched ar $r_s$, $\phi_s$, where $r_s$ satisfies Equation (3.24) with these fixed $r$, $\phi$.

43

If the incident magnetic field is perpendicular to the surface at $r_s$, $\phi_s$, then, according to Fock, the field at $r$, $\phi$ due to the surface wave launched at $r_s$, $\phi_s$ will be tangent to the geodesic and given by

$$H_T = e^{iks} \frac{1}{m} f(\zeta) , \qquad (3.25)$$

where $s$ is the path length and

$$m = \left( \frac{kR}{2} \right)^{\frac{1}{3}} , \qquad (3.26)$$

$$\zeta = \left( \frac{kr_s}{2} \cos \psi \frac{\sin \theta_0}{\sec^2 \theta_0} \right)^{\frac{1}{3}} (\phi - \phi_s) . \qquad (3.27)$$

Otherwise, if the incident magnetic field is tangent to the surface at $r_s$, $\phi_s$ the field will be perpendicular to the geodesic and given by

$$H_\perp = e^{iks} g(\zeta) . \qquad (3.28)$$

We need the projection of the magnetic polarization, $\hat{p}$, onto the perpendicular and tangent directions at the shadow boundary in order to apply the above method of computing the field. We designate these directions at the shadow boundary by

$$\hat{q}_\perp = (\cos \theta_0 \cos \phi_s , \cos \theta_0 \sin \phi_s , -\sin \theta_0 )$$

$$\hat{q}_{||} = \hat{q}_\perp \times \hat{k} . \qquad (3.29)$$

Hence, with the incident $\hat{p}$ polarization, the field $H_T$ is multiplied by $(\hat{p} \cdot \hat{q}_\perp )$ while the field $H_\perp$ is multiplied by $(\hat{p} \cdot \hat{q}_{||} )$.

There will be a contribution from each geodesic path satisfying the boundary conditions and passing through a given point. We enumerate these.

Let the point in question be specified by $r$, $\phi$ where $\phi_s \leq \phi \leq \pi$. Then, given the direction of incidence we have the possible geodesics

$$r = r_s^{(n)} \cos \psi \sec \left[ (2\pi n + \phi - \phi_s) \sin \theta_0 + \psi \right] , \quad n = 0, 1, \ldots \quad (3.30)$$

$$r = r_s^{(n')} \cos \psi \sec \left[ (2\pi n' - \phi - \phi_s) \sin \theta_0 + \psi \right] , \quad n' = 1, 2, \ldots \quad (3.31)$$

These are to be solved for $\left\{ r_s^{(n)} \right\}$ and $\left\{ r_s^{(n')} \right\}$, where we note the first set terminates at n such that

$$(2\pi n + \phi - \phi_s) \sin \theta_0 + \psi \geq \frac{\pi}{2} , \quad (3.32)$$

while the second terminates at n' such that

$$(2\pi n' - \phi - \phi_s) \sin \theta_0 + \psi \geq \frac{\pi}{2} , \quad (3.33)$$

corresponding to these will be the sets $\left\{ \xi_n \right\}$ and $\left\{ \xi_{n'} \right\}$ as well as the path lengths $\left\{ s_n \right\}$, $\left\{ s_n' \right\}$.

Since, in general, the shadow boundary does not coincide with the phase front of the incident radiation we take account of the phase by inserting the factor $e^{i\vec{k} \cdot \vec{\xi}_s (n)}$ or $e^{i\vec{k} \cdot \vec{\xi}_s (n')}$ in each case. This gives a total phase of

$$\phi_n = \vec{k} \cdot \vec{r}_s(n) + ks^{(n)} , \quad (3.34)$$

$$\phi_{n'} = \vec{k} \cdot \vec{r}_s(n') + ks^{(n')} . \quad (3.35)$$

These are explicitly

$$\phi_n = kr \sin \left[ (2\pi n + \phi - \phi_s) \sin \theta_0 + \psi \right] , \quad (3.36)$$

$$\phi_{n'} = kr \sin \left[ (2\pi n' - \phi - \phi_s) \sin \theta_0 + \psi \right] .$$

Since we will need to add the various contributions vectorially we choose to facilitate this by resolving the components of the field on the surface in the $\hat{\phi}$ and $\hat{r}$ directions. Now the field $H_T$ lies along the tangent vector

$$\hat{T} = \hat{r} \sin \left[ (\phi - \phi_s) \sin \theta_0 + \psi \right] + \hat{\phi} \cos \left[ (\phi - \phi_s) \sin \theta_0 + \psi \right] , \qquad (3.37)$$

while the field $H_\perp$ lies along the vector

$$\hat{\theta} \times \hat{T} = -\hat{\phi} \sin \left[ (\phi - \phi_s) \sin \theta_0 + \psi \right] + \hat{r} \cos \left[ (\phi - \phi_s) \sin \theta_0 + \psi \right] . \qquad (3.38)$$

These explicitly give the $\hat{r}$ and $\hat{\phi}$ components. Finally, we find the total contributions. On the surface at the point $r$, $\phi$ we have, for incident polarization $\hat{p}$ , $\qquad$ (3.39)

$$\vec{H}_1(\hat{p}) = \hat{r} \left[ \sum_{n=0} e^{i \phi_n} \left\{ (\hat{p} \cdot \hat{q}_{\shortparallel}) g(\xi_n) \cos X_n + (\hat{p} \cdot \hat{q}_\perp)(i/m_n) f(\xi_n) \sin X_n \right\} + \right.$$

$$\left. + \sum_{n=1} e^{i \phi_{n'}} \left\{ (\hat{p} \cdot \hat{q}_{\shortparallel}) g(\xi_{n'}) \cos X_n + (\hat{p} \cdot \hat{q}_\perp)(i/m_{n'}) f(\xi_{n'}) \sin X_{n'} \right\} \right] +$$

$$+ \hat{\phi} \left[ \sum_{n=0} e^{i \phi_n} \left\{ (\hat{p} \cdot \hat{q}_\perp)(i/m_n) f(\xi_n) \cos X_n - (\hat{p} \cdot \hat{q}_{\shortparallel}) g(\xi_n) \sin X_n \right\} + \right.$$

$$\left. + \sum_{n'=1} e^{i \phi_{n'}} \left\{ (\hat{p} \cdot \hat{q}_\perp)(i/m_{n'}) f(\xi_{n'}) \cos X_{n'} - (\hat{p} \cdot \hat{q}_{\shortparallel}) g(\xi_{n'}) \sin X_{n'} \right\} \right] ,$$

where we have put

$$X_n = (2\pi n + \phi - \phi_s) \sin \theta_0 + \psi$$

$$\qquad (3.40)$$

$$X_{n'} = (2\pi n' - \phi - \phi_s) \sin \theta_0 + \psi .$$

A point to note in the case of the cone is that this apparently three-dimensional problem

is, away from the tip, and according to the criterion of the Fock method, two-dimensional.

This becomes more apparent if we use a geometrical method to find the geodesic paths.

We start by unrolling the cone of angle $\theta$ by breaking it at one of the shadow boundaries
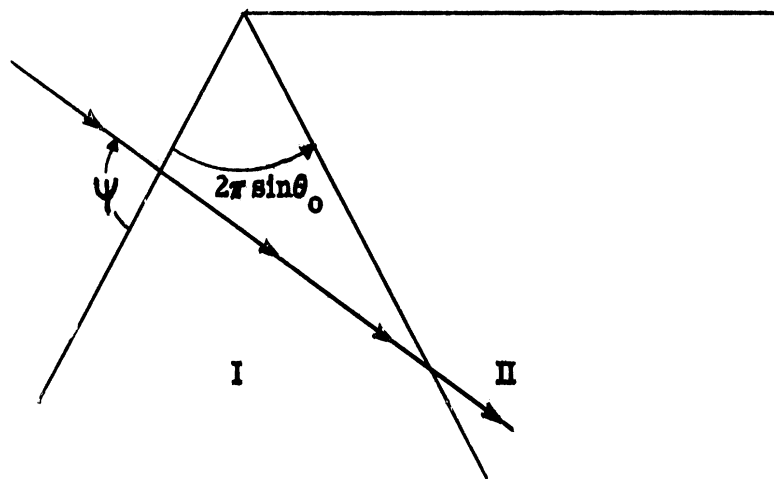

as in Figure 3.2

Figure 3.2
The Unrolled Cone

If the incident ray makes an angle $\psi$ with the shadow boundary, this ray continues unchanged

onto the unrolled surface. Then we repeat the process and find the rays wrapping around

the cone, following geodesic paths are just straight lines.

There is then no convergence or divergence of the geodesics, away from the tip, and

this is indeed a two-dimensional problem in the sense of the application of Fock's method.

This method has been used to determine the radiation pattern of an array of slots on a

cone. The computation was then compared with experiment and appears in Reference 15.

The comparison seems to establish the validity of the Fock approach.

IV

CONCLUSIONS

We can characterize the Fock approach as stemming from a local and primarily

physical analysis of the behavior of the fields at and near the geometrical shadow boundary.

This coupled with certain general considerations of the known solutions for the circular

cylinder, and the sphere give a method of treating the shadow and transition regions

provided we exclude any regions in which there is a focussing effect.

Aside from the use of the method in solving physical problems we can look on it as

giving a hint as to the form of asymptotic solutions of boundary value problems in which

the boundary is a coordinate surface in a system in which the Helmholtz equation is

separable. That is to say, we suggest that the asymptotic form of the special functions

associated with these separable boundary value problems may be found more easily if we

assume the Fock solution is what we are looking for. This approach should be cautious,

however, since some recent work of R. K. Ritt (Ref. 2) suggests that there may be a dis-

crepancy in the case of scalar scattering by a prolate spheroid.

Extensive tables of both the Fock functions have been computed by the Air Force

Cambridge Research Center under the direction of N. Logan (Ref. 16). These are for

positive values of the argument $0 \leq \zeta \leq 9.99$ in steps of $0.01$. The function $g(\zeta)$ has

been computed by Fock (Ref. 14) for $-4.5 \leq \zeta \leq 4.5$ in steps of $0.1$.

APPENDIX I

## THE CONTINUATION OF CERTAIN SOLUTIONS OF LEGENDRE'S EQUATION TO AN INFINITELY MANY SHEETED RIEMANN SURFACE

For the angular range $\frac{\pi}{6} < \theta < \frac{5\pi}{6}$ we have the representation

$$P_\nu (\cos\theta) = \frac{1}{\sqrt{\pi}} \frac{\Gamma(\nu+1)}{\Gamma(\nu+\frac{3}{2})} \left\{ e^{i\frac{\pi}{2}} \frac{e^{-i(\nu+\frac{1}{2})\theta}}{\sqrt{2i\sin\theta}} F\left(\frac{1}{2},\frac{1}{2}; \nu+\frac{3}{2}; \frac{-e^{-i\theta}}{2i\sin\theta}\right) + \right.$$

(A.1)

$$\left. + \frac{e^{i(\nu+\frac{1}{2})\theta}}{\sqrt{2i\sin\theta}} F\left(\frac{1}{2},\frac{1}{2}; \nu+\frac{3}{2}; \frac{e^{i\theta}}{2i\sin\theta}\right) \right\}$$

which is absolutely convergent in the specified range. (The series expansion is asymptotic

outside this range, i.e. for $\xi < \theta < \pi - \xi$ and $|\nu \sin \xi| \gg 1$). Let $\zeta \equiv e^{i\theta}$, thus

(A.1) becomes

$$P_\nu = \frac{1}{\sqrt{\pi}} \frac{\Gamma(\nu+1)}{\Gamma(\nu+\frac{3}{2})} \left\{ e^{i\frac{\pi}{2}} \frac{\bar{\zeta}^{\nu+\frac{1}{2}}}{\sqrt{\zeta-\bar{\zeta}}} F\left(\frac{1}{2},\frac{1}{2}; \nu+\frac{3}{2}; \frac{-\bar{\zeta}}{\zeta-\bar{\zeta}}\right) + \right.$$

(A.2)

$$\left. + \frac{\zeta^{\nu+\frac{1}{2}}}{\sqrt{\zeta-\bar{\zeta}}} F\left(\frac{1}{2},\frac{1}{2}; \nu+\frac{3}{2}; \frac{\zeta}{\zeta-\bar{\zeta}}\right) \right\} \quad .$$

Or equivalently

$$P_\nu = \frac{1}{\sqrt{\pi}} \frac{\Gamma(\nu+1)}{\Gamma(\nu+\frac{3}{2})} \left\{ e^{i\frac{\pi}{2}} \frac{\bar{\zeta}^{\nu+1}}{\sqrt{1-\bar{\zeta}^2}} F\left(\frac{1}{2},\frac{1}{2}; \nu+\frac{3}{2}; \frac{\bar{\zeta}^2}{\bar{\zeta}^2-1}\right) + \right.$$

$$\left. + e^{-i\frac{\pi}{2}} \frac{\zeta^{\nu+1}}{\sqrt{1-\zeta^2}} F\left(\frac{1}{2},\frac{1}{2}; \nu+\frac{3}{2}; \frac{\zeta^2}{\zeta^2-1}\right) \right\} \quad .$$

If now we make use of the transformation of the hypergeometric function,

$$F(a,b,c;z) = (1-z)^{-a} \, F(a,c-b;c;\frac{z}{z-1}) \quad , \qquad \text{(A.3)}$$

Equation (A.2) takes the form

$$P_\nu = \frac{1}{\sqrt{\pi}} \frac{\Gamma(\nu+1)}{\Gamma(\nu+\frac{3}{2})} \left\{ e^{i\frac{\pi}{2}} \, \zeta^{-(\nu+1)} \, F\left(\frac{1}{2}, \nu+1; \nu+\frac{3}{2}; \zeta^2\right) + \right.$$

$$\left. + \, e^{-i\frac{\pi}{2}} \, \zeta^{-(\nu+1)} \, F\left(\frac{1}{2}, \nu+1; \nu+\frac{3}{2}; \zeta^2\right) \right\} \quad . \qquad \text{(A.4)}$$

From this reduction we are led to define the functions

$$P_\nu^{(+)}(\zeta) \quad \frac{1}{\sqrt{\pi}} \frac{\Gamma(\nu+1)}{\Gamma(\nu+\frac{3}{2})} \, e^{-i\frac{\pi}{2}} \, \zeta^{\nu+1} \, F\left(\frac{1}{2}, \nu+1; \nu+\frac{3}{2}; \zeta^2\right)$$

$$\text{(A.5)}$$

$$P_\nu^{(-)}(\zeta) \quad \frac{1}{\sqrt{\pi}} \frac{\Gamma(\nu+1)}{\Gamma(\nu+\frac{3}{2})} \, e^{i\frac{\pi}{2}} \, \zeta^{\nu+1} \, F\left(\frac{1}{2}, \nu+1; \nu+\frac{3}{2}; \zeta^2\right) .$$

So that

$$P_\nu (\cos\theta) = P_\nu^{(+)} + P_\nu^{(-)} \qquad \text{(A.6)}$$

$$P_\nu^* (\cos\theta) = P_\nu (-\cos\theta) = e^{-i\nu\pi} P_\nu^{(+)} + e^{i\nu\pi} P_\nu^{(-)} \quad .$$

We also note that

$$P_\nu^{(-)}(\theta) = -P^{(+)}(-\theta) \quad . \qquad \text{(A.7)}$$

From the arguments of the hypergeometric functions we have that they are absolutely

convergent on the unit circle except at the points $\zeta \, (\zeta) = \pm 1$. They are, moreover,

periodic in $\theta$ having the period $\pi$ so that if we continue the functions $P^{(\pm)}$ past the cut $[-1, 1]$ onto an infinitely many sheeted Riemann surface we have

$$P_\nu^{(+)}(\theta + 2\pi n) = e^{2\pi n \nu}\, P_\nu^{(+)}(\theta)$$

$$P_\nu^{(-)}(\theta - 2\pi n) = e^{2\pi n \nu}\, P_\nu^{(-)}(\theta)$$

(A.8)

on the $n$th sheet.
