# STRUCTURE OF THE REACTION PRODUCT OF PENTAPHENYLGERMOLE AND DIIRON ENNEACARBONYL: $\mu$-(1-(1,2,3,4-TETRAPHENYLBUTADIENYL)PHENYLGERMYLENE)-OCTACARBONYLDIIRON(Fe-Fe) 

M. DAVID CURTIS *, WILLIAM M. BUTLER, and JOHN SCIBELLI<br>Department of Chemistry, The University of Michigan, Ann Arbor, Michigan 48109 (U.S.A.) (Received November 15th, 1979)

## Summary

Pentaphenylgermole (1-germa-1,2,3,4,5-pentaphenylcyclopenta-2,4-diene) reacts with diiron enneacarbonyl in refluxing diethyl ether to produce an orange, crystalline complex. This complex was established by single crystal X-ray diffraction to be the result of a novel hydroferration of the Ge-C $\sigma$-bond of the germacyclopentadiene moiety. The structure is of the type, $\mathrm{RR}^{\prime} \mathrm{Ge}\left[\mathrm{Fe}(\mathrm{CO})_{4}\right]_{2}$, in which R is a phenyl and $\mathrm{R}^{\prime}$ is the butadienyl fragment. The RR'Ge group bridges the $\mathrm{Fe}-\mathrm{Fe}$ bond of the $\mathrm{Fe}_{2}(\mathrm{CO})_{8}$ fragment. The coordination about each iron atom is distorted octahedral with one Fe , the Ge, and 4 CO's making up the coordination sphere. Three pairs of carbonyls are eclipsed and the structure shows severe distortions to relieve the non-bonded repulsions between these eclipsed carbonyl groups. The relevant crystal parameters are: $a$ 11.466(3), $b$ 11.228(4), $c$ 16.178(5) $\AA, \alpha$ 91.41(2), $\beta$ 108.99(2), $\gamma 101.34(2)^{\circ}, V 1922(1) \AA^{3}, \rho=1.46, Z=2$, space group $=P 1$. The final $R$-values, based 3234 reflections with $I>3 \sigma(I)$ are $R=0.079$ and $R_{\mathrm{w}}=$ 0.095 with all non-hydrogen atoms included with isotropic temperature factors except for the two iron and germanium atoms which are anisotropic. Some molecular parameters are (distances in pm ): $\mathrm{Ge}-\mathrm{Fe}^{1}, 240.8(2) ; \mathrm{Ge}-\mathrm{Fe}^{2}$, 243.0(2); $\mathrm{Fe}^{1}-\mathrm{Fe}^{2}, 278.5(3) ; \mathrm{Fe}-\mathrm{CO}, 174 \pm 2 ; \mathrm{Ge}-\mathrm{C}, 198 \pm 2, \mathrm{C}-\mathrm{O}, 117 \pm 2$; $\mathrm{Fe}^{1}-\mathrm{Ge}^{2}-\mathrm{Fe}^{2}, 70.30(8) ; \mathrm{Ge}-\mathrm{Fe}^{1}-\mathrm{Fe}^{2}$, $55.23(6) ; \mathrm{Ge}^{-} \mathrm{Fe}^{2}-\mathrm{Fe}^{\mathbf{1}}, 54.47(6)$; and $\mathrm{C}-\mathrm{Ge}-\mathrm{C}, 105.5(5)$.

## Introduction

Some years ago we were interested in stabilizing $p \pi-p \pi$ bonding between the heavier Group IV congeners and carbon by incorporating the heteroelement ( $E$ ) in a cyclic, 6- $\pi$ electron structure, e.g., a hetero-cyclopentadienide ion [1], or by coordination of the $\mathbf{C}-\mathbf{E} \pi$-system to transition metal species
[1-6]. In our hands, the latter approach was unsuccessful but has apparently been brought to fruition by Sakurai et al. [7] who have reported the synthesis of the $\pi$-silaallyliron complex, I [7] *.

(I)

However, the anion of pentaphenylgermole (III) was deduced to be chargeddelocalized, this deduction being based on the bright red color of III and the fact that pentaphenylgermole (II) is at least $10^{6}$ times more acidic than triphenylgermane [1].

Consequently, it was of some interest to determine if compound II would form $\pi$-germacyclopentadienyl metal complexes. Since cyclopentadiene reacts with metal carbonyls to give species of the type, $\left(\pi-\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{M}(\mathrm{CO})_{n}$ or $\left(\pi-\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{M}_{2}(\mathrm{CO})_{m}$, we allowed complex II to react with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$, hoping to observe the reaction shown in (3a). Instead, the reaction has now been shown to proceed as in (3b) to produce a germanium bridged, iron dimer (IV) in which a $\mathrm{Ge}-\mathrm{C} \sigma$-bond of the germole ring has been "hydroferrated", thus transforming the germole ring into an acyclic tetraphenylbutadienyl ligand.

[^0]
## Experimental

Pentaphenylgermole [1] ( 1 g ) and an equimolar amount of diiron enneacarbonyl were placed in a 100 ml Schnlenk tube under a $\mathrm{N}_{2}$ atmosphere. Fifty ml of dry diethyl ether was added and the mixture refluxed for 1.5 h , after which time the insoluble $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ had dissolved, giving a bright orange solution. The solution was concentrated and cooled to $0^{\circ} \mathrm{C}$, affording a nearly quantitative yield of large, orange crystals. These were recrystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{EtOH}$ by first dissolving the solid in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, adding EtOH , and then slowly boiling off the methylene chloride. The pure products melts at $196-197^{\circ} \mathrm{C}$ (in air) with decomposition. Anal. Found: C, 59.23 ; H, 3.18; Fe, 13.16; Ge, 10.70 and 12.05. $\mathrm{C}_{42} \mathrm{H}_{26} \mathrm{Fe}_{2} \mathrm{GeO}_{8}$ calcd.: $\mathrm{C}, 59.85 ; \mathrm{H}, 3.08 ; \mathrm{Fe}, 13.25 ; \mathrm{Ge}, 8.61 \%$; MW, Found 818, calcd. 842.7 (analyses and MW by Galbraith Laboratories, Knoxville, Tennessee).

A suitable crystal was selected, mounted on a glass fiber, and then placed on a Syntex P2 ${ }_{1}$ diffractometer * (see Table 1 for relevant statistics). Initial counter data and axial oscillation photos showed the crystals to be triclinic. With $Z=2$, the space group $P \bar{I}\left(C_{i}^{1}\right.$, No. 2) was chosen. A Patterson map revealed the location of the germanium and two iron atoms. These heavy atom positions were refined once and the subsequent difference map revealed the positions of all the remaining non-hydrogen atoms. The structure converged with all atoms isotropic after two full matrix refinements. Two more cycles with the heavy atoms anisotropic gave the final structure. On the last cycle, the largest parameter shifts were comparable to the errors in the parameters. The total number of variables in the refinement was 228, giving a data/variable ratio $=$ 14.2. The largest peak in the final difference map was $0.9 \mathrm{e} / \AA^{3}$ and appeared about $0.8 \AA$ from C13. No attempt was made to locate the hydrogen atoms. Results

The asymmetric unit consists of one molecule of the iron-germanium complex. There are no unusual intermolecular contacts. Figure 1 shows a view of the molecule down the $\mathrm{Fe}^{2}-\mathrm{Fe}^{1}$ axis and shows the atom labelling scheme. Figure 2 is an ORTEP drawing of the inner coordination spheres of the iron atoms, the germanium, and the butadienyl fragment. Also shown in Figure 2 are the primary carbons of the phenyl groups bonded to germanium and the butadienyl fragment.

Table 2 gives the atomic positions in the unit cell and the temperature factors. Table 3 gives the derived bond distances and angles, and Table $4 * *$ describes some calculated, least-squares planes. Table $5 * *$ lists the observed and calculated structure factors.

$a_{\text {Average }}$ values. Standard deviations of the averages were calculated from the formula, $\sigma=\left\{\Sigma\left(x_{n}-\bar{x}\right)^{2} /\right.$ $(n-1) 1^{1 / 2} .{ }^{b}$ The ranges of the $C-C$ bond distances and $C-C-C$ bond angles in the phenyl groups are 130-152 pm and 115-132 .

## Discussion

The reaction of pentaphenylgermole with $\mathrm{Fe}_{\mathbf{2}}(\mathrm{CO})_{9}$ results in the transfer of the hydrogen originally on the germanium to one of the $\alpha$-carbons of the germole ring with concommitant cleavage of the $\mathbf{G e}-\mathrm{C} \sigma$-bond. The resulting $\mathrm{RR}^{\prime} \mathrm{Ge}$ fragment then bridges the $\mathrm{Fe}-\mathrm{Fe}$ bond of $\mathrm{a}(\mathrm{CO})_{4} \mathrm{Fe}-\mathrm{Fe}(\mathrm{CO})_{4}$ moiety.

While such recombinations of ligands on germanium may occur when, e.g., $\mathrm{R}_{3} \mathrm{GeH}$, reacts to give $\mathrm{R}_{2} \mathrm{Ge}$ complexes [9], the nature of the cleaved organic fragment has not been established previously. In our case, the cyclic structure of the germole retains the cleavage fragment, allowing its identification. The mechanism of the transfer of hydrogen from germanium to carbon has not been established, however.

Organogermanes form an interesting series of complexes with the iron and cobalt carbonyls $[3,9,10]$ in which the $\mathbf{R}_{2}$ Ge group replaces a bridging carbonyl in the parent $\mathrm{M}_{2}(\mathrm{CO})_{n}(\mathrm{M}=\mathrm{Fe}, n=9 ; \mathrm{M}=\mathrm{Co}, n=8)$. Structure V is an example of this type of complex. A second type of dimeric iron germanium complex is typified by structure VI in which there is no formal metal-metal bond [11]. The structure of IV reported here is apparently the first structurally characterized complex of type VII although the related phenyl derivative (VII, $\mathrm{R}=\mathrm{Ph}$ ) has been reported as one of the products of the reaction of $\mathrm{Ph}_{2} \mathrm{GeH}_{2}$ with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ [12], and several related tin complexes are known and structurally characterized [13,14].

(III)

(D)

(VII)

Somewhat related structures VIII are formed from the interaction of tetraalkyldigermoxanes with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ or $\mathrm{Fe}(\mathrm{CO})_{5}$ upon photolysis [15,16].

The mixing of the orbitals of bridging $\mathrm{R}_{2} \mathrm{E}(\mathrm{E}=\mathrm{Ge}, \mathrm{Sn})$ groups with the orbitals used to form metal-metal bonds has been discussed previously, and the conclusion was drawn that the bridging groups actually contribute a net bonding interaction (in spite of apparent strain!) to the metal--metal bond [17,18]. A comparison of the structure of IV with several other types of $\mathrm{Fe}-\mathrm{Ge}$ complexes supports this earlier conclusion. Thus, the $\mathrm{Fe}-\mathrm{Fe}$ bond increases in length in the series: $(\mathrm{CO})_{3} \mathrm{Fe}(\mathrm{CO})_{3} \mathrm{Fe}(\mathrm{CO})_{3}(252.3 \mathrm{ppm}$ [19]) $<$ $(\mathrm{CO})_{3} \mathrm{Fe}(\mu-\mathrm{CO})\left(\mu-\mathrm{GePh}_{2}\right)_{2} \mathrm{Fe}(\mathrm{CO})_{3}(266.6 \mathrm{pm})<(\mathrm{CO})_{3} \mathrm{Fe}\left(\mu-\mathrm{GeMe}_{2}\right)_{3} \mathrm{Fe}(\mathrm{CO})_{3}$ ( 275.0 pm [20]) < IV ( 278.5 pm ) < VIII ( 287.6 pm ). The bridging carbonyls are more effective in strengthening the $\mathrm{Fe}-\mathrm{Fe}$ bond than bridging $\mathrm{R}_{2} \mathrm{Ge}$ groups, and in VIII, the geometry preciudes extensive interaction of the bridging groups
which lead to stabilization of the metal-metal bond (see ref. 19 for a pictorial representation of the orbital mixing).

The FeGeFe angle opens up in the above series as the $\mathrm{Fe}-\mathrm{Fe}$ bond elongates as would be expected on simple geometrical grounds, the values being $66.8^{\circ}$, $70.0^{\circ}$, and $70.30^{\circ}$ respectively for the first three germanium bridged iron complexes in the series. In compound VI the FeGeFe angle is $104.5^{\circ}$, refiecting the lack of an $\mathrm{Fe}-\mathrm{Fe}$ bond. The Fe -Ge distances show considerable variation in the structures reported, but no trends are apparent. Thus, the Fe-Ge distances in $(\mathrm{CO})_{3} \mathrm{Fe}(\mu-\mathrm{GePh})_{2}(\mu-\mathrm{CO}) \mathrm{Fe}(\mathrm{CO})_{3}$ range from 240.2 to 244.0 (242.5 $\pm 2.0$ average), 247.5 in compound VIII, 239.8 in (CO) ${ }_{3} \mathrm{Fe}\left(\mu-\mathrm{GeMe}_{2}\right)_{3} \mathrm{Fe}(\mathrm{CO})_{3}$, 240.8 and 243.0 in IV, and 249.2 in VI ( $R=E t$ ). The values found here for IV are thus in the middle of the reported range of $\mathrm{Fe}-\mathrm{Ge}$ distances.

Complexes of the type VII and VIII are extremely crowded due to the eclipsing of the carbonyl groups across the $\mathrm{Fe}-\mathrm{Ge}$ bond. The effect of this crowding is especially evident in Figures 1 and 2 which show how the $\mathrm{Fe}(\mathrm{CO})_{4}$ fragments twist relative to each other in order to relieve the non-bonded repulsions between the eclipsed carbonyl groups (see also the discussion in ref. 19).

The effect of steric crowding is also seen in the tetraphenylbutadienyl fragment. Let plane 1 be defined by the atoms C2, C3, C4, C17, and C23, and plane 2 by atoms C5, Ge, Cl, C2, C3, and C4. The phenyl groups, (C17-C22) and (C23-C28) are depressed out of the mean plane 1, probably by repulsions from the phenyl (C29-C34) attached to the germanium (see Fig. 1). Also, the dihedral angle between planes 1 and 2 is $58.2^{\circ}$. This dihedral angle represents the degree of twist around the central $\mathbf{C - C ~} \sigma$-bond of the butadiene, and this twisting can also be ascribed to repulsions from the phenyl on germanium and to $\mathrm{Ph}-\mathrm{Ph}$ repulsions across the $\mathrm{C} 2-\mathrm{C} 3$ bond. Each phenyl bonded to the butadiene group is also twisted with respect to the planes of the double bonds. The phenyls attached to C1 and C2 are twisted the most ( $62.1^{\circ}$ and $65.4^{\circ}$ with respect to plane 2). The phenyls associated with C17 and C23 are twisted $42.0^{\circ}$ and $51.6^{\circ}$ with respect to plane 1.

It is interesting to compare the structure of the butadiene fragment determined here with that of $E, E$-tetraphenylbutadiene reported by Karle and Dragonette (K-D) [21]. In the K-D structure, the molecule assumes an s-trans configuration and the double bonds are strictly coplanar. The central phenyls have a dihedral angle of $75^{\circ}$ with respect to the plane of the molecule, while the end phenyls are more nearly coplanar with dihedral angles of $34^{\circ}$. The average C -Ph distance in the K-D structure is 150 pm , compared to an average of $149 \pm 1.5$ for comparable $\mathrm{C}-\mathrm{Ph}$ bonds in the butadiene group in this structure. The central $C-C \sigma$-bond and the $C=C \pi$-bonds in the $K-D$ structure have lengths 149 and 136 pm , respectively. The comparable bond lengths in the structure determined here are 151 (C2-C3), and 134 (C1-C2) and 135 (C3-C4), respectively. Thus, in this structure, the central $\sigma$-bond is somewhat longer, and the double bonds somewhat shorter, than those in the K-D structure. These results are consistent with the loss of conjugation across the central $C-C$ bond in the $s$-gauche conformation found here compared to the s-trans conformation in the K-D structure.

In summary, pentaphenylgermole reacts with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ to give a completely unexpected product, the structure of which is consistent with previously

# proposed bonding models for bridging $\mathbf{R}_{2} \mathrm{E}$-groups. The failure to form a derivative of an $\eta^{5}$-germanacyclopentadiene can be due either to a possible thermodynamic instability of such a structure or to kinetic control of the reaction path.
