ABSTRACT: We give a framework to describe gauge theory on a certain class of commutative but non-associative fuzzy spaces. Our description is in terms of an abelian gauge connection valued in the algebra of functions on the cotangent bundle of the fuzzy space. The structure of such a gauge theory has many formal similarities with that of Yang-Mills theory. The components of the gauge connection are functions on the fuzzy space which transform in higher spin representations of the Lorentz group. In component form, the gauge theory describes an interacting theory of higher spin fields, which remains non-trivial in the limit where the fuzzy space becomes associative. In this limit, the theory can be viewed as a projection of an ordinary non-commutative Yang-Mills theory. We describe the embedding of Maxwell theory in this extended framework which follows the standard unfolding procedure for higher spin gauge theories.

1. Introduction

We formulate gauge theory on a certain class of commutative but non-associative algebras, developing the constructions initiated in [1]. These algebras correspond to so called *fuzzy spaces* which reduce to ordinary spacetime manifolds in a particular associative limit. The existence of gauge theories for such algebras can be argued indirectly from the fact that these fuzzy spaces arise in the construction of higher-dimensional D-brane worldvolumes from N zero- (or one-) branes, see for example [2]–[4]. The large N limit is the limit of classical geometry, where gauge theory on the higher-dimensional brane provides an equivalent description to the zero-brane picture. In cases where the fuzzy geometry is non-commutative but associative, such as the fuzzy 2-sphere, a higher-dimensional gauge theory can be explicitly constructed, starting from the zero-brane action, both for large N and finite N [5]. In other cases involving higher-dimensional spheres, the explicit construction of this map requires a better understanding of gauge theory on non-associative spaces [1]. In this paper we find that such gauge theories have a realisation in terms of interacting higher spin field theories.

The non-associative algebra of interest $\mathcal{A}_n^*(M)$ is a deformation of the algebra of functions $\mathcal{A}(M)$ on a D -dimensional (pseudo-)Riemannian manifold M . The $*$ denotes a non-associative product for functions on the fuzzy space whilst $n \in \mathbb{Z}_+$ provides a quantitative measure of the non-associativity (in particular $\mathcal{A}_\infty^* = \mathcal{A}$). For simplicity, we take $M = \mathbb{R}^D$ with flat metric. Most of our formulas will be independent of the signature of this metric, though we will take it to be lorentzian in discussions of gauge-fixing etc. Furthermore, although we focus on the deformation for \mathbb{R}^D , there is a conceptually straightforward generalisation for curved manifolds. For example, the deformation $\mathcal{A}_n^*(S^{2k})$ has been used in the study of even-dimensional fuzzy spheres in [6].

In section 2 we define the commutative, non-associative algebra $\mathcal{A}_n^*(\mathbb{R}^D)$ which deforms $\mathcal{A}(\mathbb{R}^D)$, and give the derivations of this algebra. In this review, we recall that the associator $(A * B) * C - A * (B * C)$ of three functions A , B and C on $\mathcal{A}_n^*(\mathbb{R}^D)$ can be written as an operator $F(A, B)$ acting on C or as an operator $E(A, C)$ acting on B . These operators have expansions in terms of derivations of the algebra (given in appendix B) and naturally appear when one attempts to construct covariant derivatives for the gauge theory. We find that an inevitable consequence of this structure is that the connection and gauge parameter have to be generalised such that they too have derivative expansions (i.e. they can be understood as functions on the deformed cotangent bundle $\mathcal{A}_n^*(T^*\mathbb{R}^D)$). The infinite number of component functions in these expansions transform as totally symmetric tensors under the Lorentz group. Consequently we find that this extended gauge theory on $\mathcal{A}_n^*(T^*\mathbb{R}^D)$ is related to higher spin gauge theory on $\mathcal{A}_n^*(\mathbb{R}^D)$. The local and global structure of this extended gauge theory is analysed in section 3.

We observe that the extended gauge theory remains non-trivial even in the limit where the non-associativity parameter goes to zero. In section 4 we describe certain physical properties in this associative limit. In particular we construct a gauge-invariant action and field equations for the extended theory using techniques related to the phase space formulation of quantum mechanics initiated by Weyl [24] and Wigner [25]. The infinite

number higher spin components of the extended gauge field become just tensors on \mathbb{R}^D in the associative limit. We describe various aspects of the extended theory in component form in order to make the connection with higher spin gauge theory more explicit. From this perspective it will be clear that the extended theory (as we have presented it) does not realise all the possible symmetries of the corresponding higher spin theory on \mathbb{R}^D . We suggest that it could describe a partially broken phase of some fully gauge-invariant theory. We then compare the structure we find with that of the interacting theory of higher spin fields discovered by Vasiliev [18]. A precise way to embed Maxwell theory in the extended theory is given. The method is identical to the unfolding procedure which has been used by Vasiliev in the context of higher spin gauge theories [20]. It can also be understood simply via a change of basis in phase space under a particular symplectic transformation.

In section 5 we describe how the extended theory in the associative limit described in section 4 is related to a projection of an ordinary non-commutative Yang-Mills theory. We also describe connections to Matrix theory. We then discuss how one might generalise the results of section 4 to construct a gauge-invariant action for the non-associative theory. Section 6 contains some concluding remarks.

2. The non-associative deformation \mathcal{A}_n^*

We begin by defining the non-associative space of interest. Following [1], we consider the commutative, non-associative algebra $\mathcal{A}_n^*(\mathbb{R}^D)$ which is a specific deformation of the commutative, associative algebra of functions $\mathcal{A}(\mathbb{R}^D)$ on \mathbb{R}^D (which is to be thought of as physical spacetime in D dimensions). Another space that will be important in forthcoming discussions is the algebra of differential operators acting on $\mathcal{A}_n^*(\mathbb{R}^D)$. This algebra is isomorphic to the deformed algebra $\mathcal{A}_n^*(T^*\mathbb{R}^D)$ of functions on the (flat) cotangent bundle $T^*\mathbb{R}^D$. This correspondence will be helpful when we come to consider gauge theory on $\mathcal{A}_n^*(\mathbb{R}^D)$.

The space \mathbb{R}^D has coordinates x^μ and flat metric. The euclidean signature metric $\delta_{\mu\nu}$ arises most directly in the Matrix theory considerations motivating [1] but the algebra can be continued to lorentzian signature by replacing this with lorentzian metric $\eta_{\mu\nu}$. The algebraic discussion in this and the next section (and in the appendices) works equally well in either signature, but some additional subtleties related to gauge-fixing discussed in section 4 are specific to the lorentzian case. The deformed algebra $\mathcal{A}_n^*(\mathbb{R}^D)$ is spanned by the infinite set of elements $\{1, x^\mu, x^{\mu_1\mu_2}, \dots\}$,¹ where each $x^{\mu_1\cdots\mu_s}$ transforms as a totally symmetric tensor of rank s under the Lorentz group. The commutative (but non-associative) product $*$ for all elements $x^{\mu_1\cdots\mu_s}$ is defined in [1] and appendix B (this appendix also defines a more general set of products with similar properties to $*$). The explicit formula is rather complicated but the important point is that $x^{\mu_1\cdots\mu_s} * x^{\nu_1\cdots\nu_t}$ equals $x^{\mu_1\cdots\mu_s\nu_1\cdots\nu_t}$ up to the addition of lower rank elements with coefficients proportional to inverse powers of n (for example $x^\mu * x^\nu = x^\nu * x^\mu = x^{\mu\nu} + \frac{1}{n}\eta^{\mu\nu}$). This means that the algebra is associative up to terms involving inverse powers of n . An immediate consequence of this structure is that

¹In [1], the elements x were called z and the deformed algebra $\mathcal{A}_n^*(\mathbb{R}^D)$ was called $\mathcal{B}_n^*(\mathbb{R}^D)$.

$\lim_{n \rightarrow \infty} \mathcal{A}_n^*(\mathbb{R}^D) = \mathcal{A}(\mathbb{R}^D)$, since $\lim_{n \rightarrow \infty} x^{\mu_1 \cdots \mu_s} = x^{\mu_1} \cdots x^{\mu_s}$ (the $*$ -product being just pointwise multiplication in this limit). Henceforth we refer to $n \rightarrow \infty$ as the *associative limit*.

Recall that symmetries of non-commutative spaces are typically generated by the subgroup of the Lorentz group corresponding to symplectic transformations preserving the non-commutativity parameter (see e.g. [23, 40]). As explained in [1] however, $\mathcal{A}_n^*(\mathbb{R}^D)$ corresponds to a milder deformation of \mathbb{R}^D since it is still commutative and the non-associativity parameter is a Lorentz scalar (proportional to $1/n$). Therefore the deformation above does not break Lorentz symmetry.

One can define derivations ∂_μ of $\mathcal{A}_n^*(\mathbb{R}^D)$ via the rule

$$\partial_\mu x^{\mu_1 \cdots \mu_s} = s \delta_\mu^{(\mu_1} x^{\mu_2 \cdots \mu_s)}, \quad (2.1)$$

where brackets denote symmetrisation of indices (with weight 1).² This definition implies that ∂_μ satisfy the Leibnitz rule when acting on $*$ -products of elements of $\mathcal{A}_n^*(\mathbb{R}^D)$. This Leibnitz property also holds with respect to the more general commutative, non-associative products described in appendix B. It is clear that composition of these derivations is a commutative *and* associative operation. In the associative $n \rightarrow \infty$ limit, ∂_μ just act as the usual partial derivatives on \mathbb{R}^D .

2.1 Functions

Functions of the coordinates $x^{\mu_1 \cdots \mu_s}$ are written $A(x) \in \mathcal{A}_n^*(\mathbb{R}^D)$. Such functions form a commutative but non-associative algebra themselves with respect to the $*$ multiplication. A quantitative measure of this non-associativity is given by the *associator*

$$[A, B, C] := (A * B) * C - A * (B * C) \quad (2.2)$$

for three functions A, B and C . Since $\mathcal{A}_n^*(\mathbb{R}^D)$ is commutative then the associator (2.2) has the antisymmetry $[A, B, C] = -[C, B, A]$. The associator also satisfies the cyclic identity $[A, B, C] + [B, C, A] + [C, A, B] \equiv 0$. An important fact noted in [1] is that such associators can be written as differential operators involving two functions acting on the third. In particular, one can define the two operators $E(A, B)$ and $F(A, B)$ via

$$\begin{aligned} [A, B, C] &=: E(A, C) B \\ &=: F(A, B) C. \end{aligned} \quad (2.3)$$

The antisymmetry property of the associator implies $E(A, B) = -E(B, A)$ and the cyclic identity implies $F(A, B) - F(B, A) = E(A, B)$. These operators have the following derivative expansions (see [1] or appendix B)

$$\begin{aligned} E(A, B) &= \sum_{s=1}^{\infty} \frac{1}{s!} (E^{\mu_1 \cdots \mu_s}(A, B))(x) * \partial_{\mu_1} \cdots \partial_{\mu_s}, \\ F(A, B) &= \sum_{s=1}^{\infty} \frac{1}{s!} (F^{\mu_1 \cdots \mu_s}(A, B))(x) * \partial_{\mu_1} \cdots \partial_{\mu_s}, \end{aligned} \quad (2.4)$$

²The derivations ∂_μ were called δ_μ in [1].

where the coefficients $E^{\mu_1 \cdots \mu_s}(A, B)$ and $F^{\mu_1 \cdots \mu_s}(A, B)$ are both polynomial functions of the algebra transforming as totally symmetric tensors under the Lorentz group.³ The properties quoted above follow for each of these coefficients so that $E^{\mu_1 \cdots \mu_s}(A, B) = -E^{\mu_1 \cdots \mu_s}(B, A)$ and $F^{\mu_1 \cdots \mu_s}(A, B) - F^{\mu_1 \cdots \mu_s}(B, A) = E^{\mu_1 \cdots \mu_s}(A, B)$. The reason there are no $s = 0$ terms in (2.4) is that the associators $[A, 1, C]$ and $[A, B, 1]$ are both identically zero. Thus since (2.4) are valid as operator equations on any function then including such zeroth order terms in (2.4) would imply their coefficients are identically zero by simply acting on a constant function. The first non-vanishing $s = 1$ coefficients in (2.4) can be expressed rather neatly as associators, such that $E^\mu(A, B) = [A, x^\mu, B]$ and $F^\mu(A, B) = [A, B, x^\mu]$. In a similar manner, all subsequent $s > 1$ coefficients in (2.4) can also be expressed in terms of (sums of) associators of A and B with coordinates $x^{\mu_1 \cdots \mu_s}$ (though we do not give explicit expressions as they are unnecessary). An important point to keep in mind is that $E(A, B)$ and $F(A, B)$ vanish in the associative limit as expected.

The algebra of the differential operators in (2.4) closes under composition and is non-associative (following non-associativity of $\mathcal{A}_n^*(\mathbb{R}^D)$) but it is also non-commutative. Since $E(A, B)$ and $F(A, B)$ vanish in the associative limit the algebra of these operators becomes trivially commutative when $n \rightarrow \infty$. As will be seen in the next subsection, more general differential operators acting on $\mathcal{A}_n^*(\mathbb{R}^D)$ also close under composition to form a non-commutative, non-associative algebra. However, this more general algebra remains non-commutative (but associative) when $n \rightarrow \infty$. For example, the commutator subalgebra of differential operators acting on \mathbb{R}^D corresponding to sections of the tangent bundle $T\mathbb{R}^D$ (i.e. vector fields over \mathbb{R}^D) is non-abelian (even though \mathbb{R}^D is itself commutative). Indeed this is often how one considers simple non-commutative geometries — as hamiltonian phase spaces of ordinary commutative position spaces (see e.g. [23]). We will draw on this analogy when we come to construct a gauge theory on $\mathcal{A}_n^*(\mathbb{R}^D)$.

2.2 Differential operators

General differential operators acting on $\mathcal{A}_n^*(\mathbb{R}^D)$ are written

$$\hat{A} = \sum_{s=0}^{\infty} \frac{1}{s!} A^{\mu_1 \cdots \mu_s}(x) * \partial_{\mu_1} \cdots \partial_{\mu_s}, \quad (2.5)$$

where $A^{\mu_1 \cdots \mu_s}$ are functions of the algebra transforming as totally symmetric tensors under the Lorentz group. It is clear that such operators can equivalently be viewed as elements of the deformed algebra $\mathcal{A}_n^*(T^*\mathbb{R}^D)$ of functions on the cotangent bundle $T^*\mathbb{R}^D$. In the associative limit, $\mathcal{A}_\infty^*(T^*\mathbb{R}^D)$ is just the Weyl algebra of \mathbb{R}^D (i.e. the infinite-dimensional universal enveloping algebra of the Heisenberg algebra in D -dimensions spanned by all polynomials of coordinates x^μ and partial derivatives ∂_μ). Because of this $\mathcal{A}_n^*(T^*\mathbb{R}^D)$ may also be thought of as a *deformed Weyl algebra*.

Just as in (2.4), the general operators (2.5) also close under composition to form a non-commutative and non-associative algebra. The operator realisations $E(A, B)$ and

³The $*$ -product in the expression for the operators (2.4) means act first on a function with the derivatives, then $*$ -multiply this differentiated function with the coefficients (for each s in the sum).

$F(A, B)$ (2.3) of the associator of functions have useful generalisations to the case where functions A and B are replaced by operators \hat{A} and \hat{B} respectively. In particular, we define

$$\begin{aligned}\hat{E}(\hat{A}, \hat{B})C &:= \hat{B}(\hat{A}C) - \hat{A}(\hat{B}C), \\ \hat{F}(\hat{A}, \hat{B})C &:= [\hat{A}, \hat{B}, C] = (\hat{A}\hat{B})C - \hat{A}(\hat{B}C),\end{aligned}\tag{2.6}$$

where C is a function. The definition of \hat{F} still involves the associator (just as in (2.3)). Notice though that the definition of \hat{E} does not involve the associator $[\hat{A}, C, \hat{B}] = (\hat{A}C)\hat{B} - \hat{A}(C\hat{B})$ directly since the algebra of differential operators is non-commutative. It is the \hat{E} operator defined in (2.6), however, that will be of interest in the forthcoming discussion. This new definition reduces to the usual associator definition (2.3) when $\hat{A} = A$ and $\hat{B} = B$ (since the algebra of functions is commutative). The definitions (2.6) obey the identities $\hat{E}(\hat{A}, \hat{B}) \equiv -\hat{E}(\hat{B}, \hat{A})$ and $\hat{F}(\hat{A}, \hat{B}) - \hat{F}(\hat{B}, \hat{A}) \equiv \hat{E}(\hat{A}, \hat{B}) + [\hat{A}, \hat{B}]$ (where $[\hat{A}, \hat{B}] := \hat{A}\hat{B} - \hat{B}\hat{A}$ is just the commutator of operators). These reduce to the identities found earlier in terms of functions when $\hat{A} = A$ and $\hat{B} = B$. In the associative limit, notice that $\hat{F}(\hat{A}, \hat{B})$ vanishes identically whilst $\hat{E}(\hat{A}, \hat{B})$ reduces to the commutator $[\hat{B}, \hat{A}]$.

The explicit derivative expansion for $\hat{E}(\hat{A}, \hat{B})$ is given in appendix A for later reference (the corresponding expression for $\hat{F}(\hat{A}, \hat{B})$ will not be needed). We should just conclude this review of the relevant algebras associated with $\mathcal{A}_n^*(\mathbb{R}^D)$ by noting that, unlike (2.4), the operator expression for $\hat{E}(\hat{A}, \hat{B})$ includes a non-vanishing zeroth order algebraic term. It is easy to see that this is so by considering C in (2.6) to be the constant function. In this case all derivative terms in $\hat{E}(\hat{A}, \hat{B})$ on the left hand side vanish whilst the right hand side reduces to the non-vanishing function $\hat{B}A - \hat{A}B$ (where A and B are the zeroth order parts of \hat{A} and \hat{B} respectively). Thus the zeroth order part $\hat{E}(\hat{A}, \hat{B})_{(0)} = \hat{B}A - \hat{A}B$, which vanishes when $\hat{A} = A$ and $\hat{B} = B$ as expected.

3. Non-associative gauge theory

We begin this section by reviewing the subtleties raised in [1] associated with formulating an abelian gauge theory on $\mathcal{A}_n^*(\mathbb{R}^D)$. We show that a naive formulation is not possible on this non-associative space. Instead it is rather natural to consider an extension of such an abelian gauge theory on the deformed algebra $\mathcal{A}_n^*(T^*\mathbb{R}^D)$ of functions on the cotangent bundle. We describe the local and global gauge structure of this non-associative extended theory. We find the structure to be similar to that of a Yang-Mills theory with infinite-dimensional gauge group. We will return to the question of embedding an abelian gauge theory on $\mathcal{A}_n^*(\mathbb{R}^D)$ in this extended structure in later sections.

3.1 Abelian gauge theory on $\mathcal{A}_n^*(\mathbb{R}^D)$

A necessary ingredient in the construction of any gauge theory is the concept of a gauge-covariant derivative. Consider a field Φ which is a function of $\mathcal{A}_n^*(\mathbb{R}^D)$ and define it to have the infinitesimal gauge transformation law

$$\delta\Phi = \epsilon * \Phi,\tag{3.1}$$

where ϵ is an arbitrary polynomial function of $\mathcal{A}_n^*(\mathbb{R}^D)$. (One reason for the choice of (3.1) is that it is reminiscent of the infinitesimal gauge transformation for a field in the fundamental representation of the gauge group in ordinary Yang-Mills theory.) An operator D_μ that is covariant with respect to (3.1) must therefore obey

$$\delta(D_\mu \Phi) = \epsilon * (D_\mu \Phi). \quad (3.2)$$

Clearly the derivation ∂_μ (2.1) alone does not obey this covariance requirement since $\delta(\partial_\mu \Phi) = \epsilon * (\partial_\mu \Phi) + (\partial_\mu \epsilon) * \Phi$. To compensate we must introduce a gauge connection A_μ , which we take to be a function on $\mathcal{A}_n^*(\mathbb{R}^D)$ and which transforms such that $\delta(A_\mu * \Phi) = \epsilon * (A_\mu * \Phi) - (\partial_\mu \epsilon) * \Phi$. Clearly the existence of such an A_μ would imply that

$$D_\mu \Phi := \partial_\mu \Phi + A_\mu * \Phi \quad (3.3)$$

indeed defines a covariant derivative on functions, satisfying (3.2). Using (3.1) then implies that we require A_μ to transform such that

$$(\delta A_\mu) * \Phi = -(\partial_\mu \epsilon) * \Phi + \epsilon * (A_\mu * \Phi) - A_\mu * (\epsilon * \Phi). \quad (3.4)$$

In ordinary gauge theory (3.4) would allow one to simply read off the necessary gauge transformation for A_μ but here things are more complicated due to non-associativity. In particular, notice that the last two terms in (3.4) can be written as the associator $[A_\mu, \Phi, \epsilon]$ and therefore, using (2.3), we require

$$\delta A_\mu = -(\partial_\mu \epsilon) + E(A_\mu, \epsilon). \quad (3.5)$$

This requirement, however, leads to a contradiction since the first two terms in (3.5) are algebraic functions on $\mathcal{A}_n^*(\mathbb{R}^D)$ whilst (2.4) tells us that the third term acts only as a differential operator on $\mathcal{A}_n^*(\mathbb{R}^D)$. Therefore such an A_μ can only exist when $E(A_\mu, \epsilon) = 0$, i.e. in the associative limit where this would simply be an abelian gauge theory on \mathbb{R}^D !

As indicated in [1], the most conservative way to proceed is therefore to simply generalise the gauge connection A_μ from an algebraic function to a differential operator \hat{A}_μ with derivative expansion

$$\hat{A}_\mu = \sum_{s=0}^{\infty} \frac{1}{s!} A_\mu^{\alpha_1 \dots \alpha_s}(x) * \partial_{\alpha_1} \dots \partial_{\alpha_s}, \quad (3.6)$$

where each component $A_\mu^{\alpha_1 \dots \alpha_s}$ is an algebraic function on $\mathcal{A}_n^*(\mathbb{R}^D)$ which transforms in the $(GL(D, \mathbb{R})\text{-reducible})$ tensor product representation corresponding to a vector times a totally symmetric rank- s tensor of the Lorentz group (we denote this representation $(1) \otimes (s)$). Unlike the associator operators (2.4), there is no reason not to include all possible terms in the sum (3.6). Indeed, in the associative limit, we will see that the only algebraic $s = 0$ term A_μ has the interpretation of an abelian gauge field embedded in this extended theory. In a similar manner one can also generalise the gauge parameter ϵ to a differential operator $\hat{\epsilon}$ with derivative expansion

$$\hat{\epsilon} = \sum_{s=0}^{\infty} \frac{1}{s!} \epsilon^{\alpha_1 \dots \alpha_s}(x) * \partial_{\alpha_1} \dots \partial_{\alpha_s}. \quad (3.7)$$

As noted already, the algebra of such operators is both non-associative and non-commutative. Consequently we must take care when revising the arguments of this subsection in terms of these extended fields. This revised analysis is described, in the next subsection, within the framework of global gauge transformations for the extended theory.

In concluding, it is important to stress that the generalisation we have made is a modification of the original theory and therefore the extended theory need not trivially reduce to an abelian gauge theory on \mathbb{R}^D in the associative limit. (Notice that the $s > 0$ terms in (3.6) and (3.7) do not vanish as $n \rightarrow \infty$.) Indeed we will find it does not though we will give a precise way to embed the abelian theory in its extension on \mathbb{R}^D .

3.2 Global structure

Consider again a field Φ which is a function of $\mathcal{A}_n^*(\mathbb{R}^D)$ but now with infinitesimal gauge transformation law

$$\delta\Phi = \hat{\epsilon}\Phi, \quad (3.8)$$

where $\hat{\epsilon}$ is the extended differential operator (3.7). Formally this is similar to Yang-Mills theory where one then obtains the global gauge transformation by exponentiating the local (Lie algebra valued) gauge parameter to obtain a general Lie group element (or more precisely the fundamental representations of these quantities). The main difference here is that the algebra of local gauge transformations (3.8) is non-associative. Despite this, given a general differential operator $\hat{\epsilon}$, there still exists a well-defined exponential $\exp(\hat{\epsilon})$ [22]. The construction essentially just follows the power series definition of the exponential map for matrix algebras but here one must choose an ordering for powers of $\hat{\epsilon}$ (so as to avoid the potential ambiguities due to non-associativity). We follow [22] and define powers via a “left action” rule so that

$$\exp(\hat{\epsilon})\Phi := \Phi + \hat{\epsilon}\Phi + \frac{1}{2}\hat{\epsilon}(\hat{\epsilon}\Phi) + \frac{1}{3!}\hat{\epsilon}(\hat{\epsilon}(\hat{\epsilon}\Phi)) + \dots, \quad (3.9)$$

for any function Φ . It is then clear that the exponentiated operator $\hat{g} := \exp(\hat{\epsilon})$ is also a differential operator acting on the algebra (albeit a rather complicated function of $\hat{\epsilon}$) and we define the “global” transformation of Φ to be

$$\Phi \rightarrow \hat{g}\Phi. \quad (3.10)$$

This transformation obviously reduces to (3.8) in some neighbourhood of the identity where $\hat{g} = 1 + \hat{\epsilon}$ (the “identity” here is the unit element of $\mathcal{A}_n^*(\mathbb{R}^D)$). The set of all transformations (3.10) does not quite form a group under left action composition since it fails to satisfy the associativity axiom (due to non-associativity of the algebra). However, all the other group axioms are satisfied.⁴

⁴Closure under composition follows using an extension of the Baker-Campbell-Hausdorff formula whereby the composition of two exponentials can itself be expressed as an exponential with the exponent being the sum of the two original exponents plus corrections involving commutators and associators of these exponents. As already mentioned above, the identity element is simply the unit element of $\mathcal{A}_n^*(\mathbb{R}^D)$. Every element $\hat{g} = \exp(\hat{\epsilon})$ has the left inverse $\hat{g}^{-1} := \exp(-\hat{\epsilon})$ which satisfies $\hat{g}^{-1}(\hat{g}\Phi) = \hat{g}(\hat{g}^{-1}\Phi) = \Phi$ for any function Φ . Thus $\hat{g}^{-1} = 1 - \hat{\epsilon}$ locally.

The derivation ∂_μ is not covariant with respect (3.10) since this transformation implies $\partial_\mu \Phi \rightarrow [\partial_\mu, \hat{g}] \Phi + \hat{g}(\partial_\mu \Phi)$. As noted at the end of the previous subsection, we therefore introduce a gauge connection \hat{A}_μ which must transform such that $\hat{A}_\mu \Phi \rightarrow -[\partial_\mu, \hat{g}] \Phi + \hat{g}(\hat{A}_\mu \Phi)$ in order that

$$\hat{D}_\mu \Phi := \partial_\mu \Phi + \hat{A}_\mu \Phi \quad (3.11)$$

transforms covariantly under (3.10). This necessary gauge transformation of $\hat{A}_\mu \Phi$ under (3.10) can be realised provided the gauge transformation of \hat{A}_μ is defined such that

$$\hat{A}_\mu \Phi \rightarrow -[\partial_\mu, \hat{g}](\hat{g}^{-1} \Phi') + \hat{g}(\hat{A}_\mu(\hat{g}^{-1} \Phi')) \quad (3.12)$$

under the more general function transformation $\Phi \rightarrow \Phi'$. This gives the desired gauge transformation when $\Phi' = \hat{g}\Phi$. One can obtain the gauge transformation of \hat{A}_μ itself by using the operator \hat{F} (2.6) to rearrange the brackets in (3.12). In particular, notice that the right hand side of (3.12) can be written

$$\begin{aligned} \left(-[\partial_\mu, \hat{g}] + \hat{g}\hat{A}_\mu - \hat{F}(\hat{g}, \hat{A}_\mu) \right) (\hat{g}^{-1} \Phi') = & \left(\left(-[\partial_\mu, \hat{g}] + \hat{g}\hat{A}_\mu - \hat{F}(\hat{g}, \hat{A}_\mu) \right) \hat{g}^{-1} \right) \Phi' - \\ & - \hat{F} \left(\left(-[\partial_\mu, \hat{g}] + \hat{g}\hat{A}_\mu - \hat{F}(\hat{g}, \hat{A}_\mu) \right), \hat{g}^{-1} \right) \Phi'. \end{aligned} \quad (3.13)$$

Therefore \hat{A}_μ must have the following gauge transformation

$$\hat{A}_\mu \rightarrow \left(-[\partial_\mu, \hat{g}] + \hat{g}\hat{A}_\mu - \hat{F}(\hat{g}, \hat{A}_\mu) \right) \hat{g}^{-1} - \hat{F} \left(\left(-[\partial_\mu, \hat{g}] + \hat{g}\hat{A}_\mu - \hat{F}(\hat{g}, \hat{A}_\mu) \right), \hat{g}^{-1} \right). \quad (3.14)$$

Setting $\hat{g} = 1 + \hat{\epsilon}$ in (3.14) leads to the infinitesimal form of the gauge transformation

$$\delta \hat{A}_\mu = -[\partial_\mu, \hat{\epsilon}] + \hat{E}(\hat{A}_\mu, \hat{\epsilon}). \quad (3.15)$$

Of course, at the infinitesimal level, this transformation equivalently follows by the requirement that $\delta(\hat{D}_\mu \Phi) = \hat{\epsilon}(\hat{D}_\mu \Phi)$ under (3.8).

Notice that (3.14) and (3.15) do not quite take the form one would expect by naively following the Yang-Mills analogy (that is they differ from what one might expect by associator terms). This is a consequence of the non-associativity of the underlying algebra of functions. In the following section we will find that the expected Yang-Mills type structure follows exactly in the associative limit.

In the discussion above we have only defined covariant derivatives \hat{D}_μ on functions and not on differential operators. Although not of the standard Yang-Mills form, (minus) the right hand side of (3.15) can still be taken as the definition for the action of the covariant derivative on operator $\hat{\epsilon}$, such that

$$\hat{D}_\mu \cdot \hat{\epsilon} := [\partial_\mu, \hat{\epsilon}] + \hat{E}(\hat{\epsilon}, \hat{A}_\mu). \quad (3.16)$$

This statement is partially justified by the fact that \hat{D}_μ then satisfies the Leibnitz rule $\hat{D}_\mu(\hat{\epsilon}\Phi) = (\hat{D}_\mu \cdot \hat{\epsilon})\Phi + \hat{\epsilon}(\hat{D}_\mu \Phi)$ (for general operator $\hat{\epsilon}$ and function Φ).⁵

⁵It should be noted that the naive commutator action $[\partial_\mu + \hat{A}_\mu, \hat{\epsilon}]$ on an operator $\hat{\epsilon}$ fails to satisfy the Leibnitz rule due to associator terms. The commutator action is identical to the covariant derivative proposed above in the associative limit.

Based on the transformation law found above, we define the *field strength* $\hat{F}_{\mu\nu}$ as

$$\hat{F}_{\mu\nu} := \hat{E}(\hat{D}_\nu, \hat{D}_\mu) = [\partial_\mu, \hat{A}_\nu] - [\partial_\nu, \hat{A}_\mu] + \hat{E}(\hat{A}_\nu, \hat{A}_\mu). \quad (3.17)$$

It is clear from this definition that $\hat{F}_{\mu\nu}$ is indeed a differential operator which transforms as a two-form under the Lorentz group. In addition, since the gauge transformations above imply that

$$\hat{D}_\mu \Phi \rightarrow \hat{g}(\hat{D}_\mu(\hat{g}^{-1}\Phi')), \quad (3.18)$$

under (3.12), then it follows that $\hat{F}_{\mu\nu}\Phi = \hat{D}_\mu(\hat{D}_\nu\Phi) - \hat{D}_\nu(\hat{D}_\mu\Phi)$ transforms as

$$\hat{F}_{\mu\nu}\Phi \rightarrow \hat{g}(\hat{F}_{\mu\nu}(\hat{g}^{-1}\Phi')), \quad (3.19)$$

and is therefore also gauge-covariant when $\Phi' = \hat{g}\Phi$. The infinitesimal form of the covariant gauge transformation of $\hat{F}_{\mu\nu}$ is

$$\delta\hat{F}_{\mu\nu} = \hat{E}(\hat{F}_{\mu\nu}, \hat{\epsilon}). \quad (3.20)$$

From the evidence above, it is clear that there are various subtleties related to the non-associative nature of the theory. Indeed the non-associativity complicates matters even further in the description of more physical aspects of the theory like lagrangians, field equations and the embedding of an abelian gauge theory in this extended framework. Recall though that this extended theory should have a non-trivial structure, even in the associative limit. We therefore postpone further discussion of the non-associative extended theory to analyse its associative limit in more detail.

4. Gauge theory on $T^*\mathbb{R}^D$ and higher spin gauge theory on \mathbb{R}^D

We begin this section by briefly summarising the results of the previous subsection in the associative limit. We then describe how one can construct a gauge-invariant action and equations of motion for this theory. Writing the extended gauge field \hat{A}_μ in terms of component functions $A_\mu^{\alpha_1 \dots \alpha_s}$ we find that the extended theory describes an interacting theory involving an infinite number of higher spin fields. When written in component form, it will be clear that the extended theory (as we have described it) does not realise all the possible symmetries of the corresponding higher spin gauge theory. We suggest that the extended theory could correspond to a partially broken phase of some fully gauge-invariant higher spin theory. A comparison of the structure we find with that of the interacting theory of higher spin fields discovered by Vasiliev [18] is then given. We conclude the section by showing how an abelian gauge theory can be embedded in this extended framework. The embedding is related to the unfolding procedure used by Vasiliev in the context of higher spin gauge theory [20].

4.1 The associative limit

Many expressions found in the previous section retain their schematic form in the associative limit. For example, the gauge transformations for functions are just as in (3.8), (3.10)

though Φ is now simply a function on \mathbb{R}^D whilst operators like $\hat{\epsilon}$ in (3.7) now have the expansion

$$\hat{\epsilon} = \sum_{s=0}^{\infty} \frac{1}{s!} \epsilon^{\alpha_1 \dots \alpha_s}(x) \partial_{\alpha_1} \dots \partial_{\alpha_s}, \quad (4.1)$$

in terms of an infinite number of functions $\epsilon^{\alpha_1 \dots \alpha_s}$ on \mathbb{R}^D (which still transform as totally symmetric tensors under the Lorentz group). It should also be noted that the set of gauge transformations (3.10) now form a group since the associativity axiom is no longer violated in this limit.

Recall that the associator operators E , F and \hat{F} in (2.4), (2.6) vanish in the associative limit whilst $\hat{E}(\hat{A}, \hat{B})$ reduces to the commutator $[\hat{B}, \hat{A}]$. Consequently the gauge transformation (3.14) takes the more familiar Yang-Mills form

$$\hat{A}_\mu \rightarrow -[\partial_\mu, \hat{g}] \hat{g}^{-1} + \hat{g} \hat{A}_\mu \hat{g}^{-1}. \quad (4.2)$$

This reduces to the infinitesimal variation

$$\delta \hat{A}_\mu = -[\partial_\mu + \hat{A}_\mu, \hat{\epsilon}]. \quad (4.3)$$

As explained earlier, from this transformation we define the action of the covariant derivative $\hat{D}_\mu = \partial_\mu + \hat{A}_\mu$ on operators $\hat{\epsilon}$ to be $\hat{D}_\mu \cdot \hat{\epsilon} := [\hat{D}_\mu, \hat{\epsilon}]$.

Since connections and gauge parameters are functions of both x and ∂ then the associative limit of the extended theory in D dimensions is also related to Yang-Mills theory on a $2D$ -dimensional non-commutative space. This connection will be clarified in section 5.1.

The transformation (4.2) implies that \hat{D}_μ indeed transforms covariantly as

$$\hat{D}_\mu \rightarrow \hat{g} \hat{D}_\mu \hat{g}^{-1}. \quad (4.4)$$

Hence the field strength (3.17)

$$\hat{F}_{\mu\nu} = [\hat{D}_\mu, \hat{D}_\nu] = [\partial_\mu, \hat{A}_\nu] - [\partial_\nu, \hat{A}_\mu] + [\hat{A}_\mu, \hat{A}_\nu], \quad (4.5)$$

also transforms covariantly. The infinitesimal form of this covariant transformation being

$$\delta \hat{F}_{\mu\nu} = [\hat{\epsilon}, \hat{F}_{\mu\nu}]. \quad (4.6)$$

4.2 Action and field equations

A simple equation of motion to consider for the extended theory in the associative limit is

$$[\hat{D}^\mu, \hat{F}_{\mu\nu}] = 0. \quad (4.7)$$

This is the field equation one would expect from following the Yang-Mills type structure found for the extended theory in the previous subsection. The equation (4.7) is invariant under the gauge transformation (4.2). Moreover it is this equation (rather than, say, the also gauge-invariant equation $\hat{D}^\mu \hat{F}_{\mu\nu} = 0$) which reduces to the correct Maxwell equation as we will see in section 4.5.

Following the Yang-Mills analogy further, a natural gauge-invariant action to consider is of the form

$$-\frac{1}{4} \text{Tr} \left(\hat{F}_{\mu\nu} \hat{F}^{\mu\nu} \right). \quad (4.8)$$

Such an action can be constructed for the extended theory we are considering provided there exists a well-defined map

$$\text{Tr} : \mathcal{A}(T^*\mathbb{R}^D) \rightarrow \mathbb{R}. \quad (4.9)$$

Furthermore, since we are now dealing with an associative theory, it is clear that an action (4.8) would be gauge-invariant provided the map (4.9) is symmetric, such that it satisfies

$$\text{Tr}(\hat{A}\hat{B}) = \text{Tr}(\hat{B}\hat{A}), \quad (4.10)$$

for any differential operators \hat{A} and \hat{B} . The next task is therefore to show that such a symmetric map exists.

Before going into the details of the map we should make a few remarks. Firstly, notice that we write the map Tr which alludes to the Yang-Mills analogy where it simply consists of taking the usual gauge-invariant trace (using the Cartan-Killing metric for the gauge group) followed by integrating over spacetime. However, we do not assume a priori that the map (4.9) can be factorised in this way.⁶ In the Yang-Mills case the symmetry property of Tr simply follows from the fact that the trace is symmetric. The symmetry of the trace is a rather general property of finite-dimensional representations — as one considers for Yang-Mills theories with compact gauge groups — since such representations can be expressed in terms of finite-dimensional square matrices (and for two such matrices X, Y , the trace of XY is just $X_j^i Y_i^j = Y_j^i X_i^j$). For the extended theory we are considering though fields are valued in the algebra of differential operators on \mathbb{R}^D and the situation is very different for the case of such infinite-dimensional representations. For example, in quantum mechanics, if the Heisenberg algebra $[\hat{x}, \hat{p}] = i$ had any representations of finite dimension $n \neq 0$ (and hence a symmetric trace) then it would imply the well-known contradiction $0 = in$!

The example above is quite pertinent since we will now show that fields in the extended theory we are considering are related to certain functions in the formulation of quantum mechanics based on the original work of Weyl [24] and Wigner [25] which was later developed by Groenewold [27] and Moyal [28] (see [31] for a nice review). Within this framework, there exists a natural concept of the symmetric map Tr . In terms of the abstract canonically conjugate operators \hat{x}^μ and \hat{p}_μ , a general operator \hat{A} of the form (4.1) is written

$$\hat{A} = A(\hat{x}, \hat{p}) = \sum_{s=0}^{\infty} \frac{i^s}{s!} A^{\alpha_1 \dots \alpha_s}(\hat{x}) \hat{p}_{\alpha_1} \dots \hat{p}_{\alpha_s}. \quad (4.11)$$

Such objects form the most general set of operators for a quantum mechanical system on \mathbb{R}^D . These operators can be given definite Hermiticity properties by simply reordering \hat{x} and \hat{p} appropriately in (4.11) at the expense of changing the values of the coefficients in

⁶As explained in [23], non-commutative gauge theories provide a counter example where such a factorisation of Tr is not possible.

the expansion of a general $A(\hat{x}, \hat{p})$. Of course this would put restrictions on the kind of coefficient functions $A^{\alpha_1 \dots \alpha_s}$ permitted in (4.11). Let us therefore just proceed with the “ \hat{p} to the right” ordering prescription above.⁷

Given this ordering rule, the *Weyl homomorphism* [24] says that every operator $A(\hat{x}, \hat{p})$ (4.11) is naturally associated with an ordinary c-number function \tilde{A} on the classical phase space \mathbb{R}^{2D} (spanned by coordinates (x, p)), such that

$$A(\hat{x}, \hat{p}) = \frac{1}{(2\pi)^{2D}} \int dy dq dx dp \tilde{A}(x, p) \exp(i q_\mu (\hat{x}^\mu - x^\mu)) \exp(i y^\mu (\hat{p}_\mu - p_\mu)). \quad (4.12)$$

The operator \hat{A} and function \tilde{A} in (4.12) are then said to be *Weyl-dual*. For the ordering rule we have chosen, notice that the q and y integrals can be evaluated in (4.12) to give the formal Dirac delta functions $\delta(\hat{x} - x)$ and $\delta(\hat{p} - p)$ respectively. Since these delta functions involve the operators \hat{x} and \hat{p} , they do not commute. Their arrangement in (4.12) clearly respects our ordering rule. Therefore, for example, if \tilde{A} is a polynomial function of the phase space variables x and p then (4.12) says that the corresponding operator function A is exactly the same polynomial function, but of the operators \hat{x} and \hat{p} respectively – with the \hat{p} operators ordered to the right. In particular this means that (4.12) relates the operators \hat{x}^μ and \hat{p}_ν to the classical phase space coordinates x^μ and p_ν respectively. The coefficient position operators $A^{\alpha_1 \dots \alpha_s}(\hat{x})$ in (4.11) can therefore also be written in terms of the function \tilde{A} , such that

$$A^{\alpha_1 \dots \alpha_s}(\hat{x}) = \frac{1}{(2\pi)^{2D}} \int dy dq dx dp \tilde{A}(x, p) y^{\alpha_1} \dots y^{\alpha_s} \exp(i q_\mu (\hat{x}^\mu - x^\mu) - i y^\mu p_\mu). \quad (4.13)$$

The trace Tr of the operator $A(\hat{x}, \hat{p})$ is defined by

$$\text{Tr}(\hat{A}) := \int dx dp \tilde{A}(x, p). \quad (4.14)$$

This integral is only defined for functions \tilde{A} with suitably rapid asymptotic decay properties. We will describe a particular *Wigner basis* for a class of such integrable functions in the next subsection.

The inverse of the relation (4.12) can then be expressed in terms of this trace, such that

$$\tilde{A}(x, p) = \frac{1}{(2\pi)^{2D}} \int dy dq \exp(i (q_\mu x^\mu + y^\mu p_\mu)) \text{Tr} \left(\exp(-i q_\mu \hat{x}^\mu) \hat{A} \exp(-i y^\mu \hat{p}_\mu) \right). \quad (4.15)$$

That (4.12) defines a homomorphism was first noted by von Neumann [26]. It follows from the fact that, given two operators \hat{A} and \hat{B} (of the form (4.11)) with respective Weyl-dual functions \tilde{A} and \tilde{B} , then one can find a new function denoted $\tilde{A} \star \tilde{B}$ which is related to

⁷This prescription is sometimes referred to as *standard ordering* and was considered originally by Mehta [29]. An alternative prescription (considered by [31] and the references therein) is the totally symmetric *Weyl ordering* of \hat{x} and \hat{p} in a given operator. Weyl ordering guarantees that operators are Hermitean. We are very grateful to C. Zachos for pointing out the comprehensive review by Lee [30] of the precise relationships between the various possible ordering prescriptions.

the operator product $\hat{A}\hat{B}$ precisely as in (4.12) (i.e. $\hat{A}\hat{B}$ and $\tilde{A} \star \tilde{B}$ are also Weyl-dual).⁸ The \star in the Weyl-dual function mentioned above denotes the so called Moyal product [27] of two functions on phase space with respect to the standard ordering of Mehta [29] we are using. This \star -product of phase space functions should not be confused with the \ast -product of elements of the fuzzy space $\mathcal{A}_n^*(\mathbb{R}^D)$ used earlier. The \star -product is non-commutative and associative (as one would expect since these properties are also true of the operator product). The action of this product between functions can be expressed succinctly in terms of the following exponentiated differential operator

$$\star = \exp \left(-i \frac{\overleftarrow{\partial}}{\partial p_\mu} \frac{\overrightarrow{\partial}}{\partial x^\mu} \right), \quad (4.16)$$

where a left (right) pointing arrow denotes the action of that derivative on the function to the left (right) of the \star -product only.⁹ More specifically, given two functions \tilde{A} and \tilde{B} then

$$\tilde{A} \star \tilde{B} = \sum_{m=0}^{\infty} \frac{1}{m!} (-i)^m \left(\frac{\partial}{\partial p_{\mu_1}} \cdots \frac{\partial}{\partial p_{\mu_m}} \tilde{A} \right) \left(\frac{\partial}{\partial x^{\mu_1}} \cdots \frac{\partial}{\partial x^{\mu_m}} \tilde{B} \right). \quad (4.17)$$

Notice in particular that the $m = 0$ term in (4.17) is just the commutative classical product of functions $\tilde{A}\tilde{B}$. The $m > 0$ terms are not commutative but are invariant under the combined exchange $\tilde{A} \leftrightarrow \tilde{B}$ and $x \leftrightarrow p$. Equation (4.17) implies that $x^\mu \star p_\nu = x^\mu p_\nu$ and $p_\nu \star x^\mu = x^\mu p_\nu - i \delta_\nu^\mu$, thus confirming that the \star -product of functions preserves the structure of the Heisenberg algebra. It is also worth noting that partial derivatives (with respect to x or p) act as derivations on the algebra of classical phase space functions with \star -product since they obey the Leibnitz rule when acting on (4.17).

The definition (4.17) implies that

$$\int dx dp (\tilde{A} \star \tilde{B})(x, p) = \int dx dp \tilde{A}'(x, p) \tilde{B}'(x, p) = \int dx dp (\tilde{B} \star \tilde{A})(x, p), \quad (4.18)$$

where the primed phase space functions denote $\tilde{A}' := \exp \left(\frac{i}{2} \frac{\partial}{\partial x^\mu} \frac{\partial}{\partial p_\mu} \right) \tilde{A}$ and $\tilde{B}' := \exp \left(\frac{i}{2} \frac{\partial}{\partial x^\mu} \frac{\partial}{\partial p_\mu} \right) \tilde{B}$ which are just multiplied with respect to the classical product in (4.18). Thus the trace (4.14) of the operator product $\hat{A}\hat{B}$ is indeed symmetric, as required.

The precise form of the gauge-invariant action (4.8) is therefore given by

$$-\frac{1}{4} \text{Tr} \left(\hat{F}_{\mu\nu} \hat{F}^{\mu\nu} \right) = -\frac{1}{4} \int dx dp \tilde{F}'_{\mu\nu}(x, p) \tilde{F}'^{\mu\nu}(x, p), \quad (4.19)$$

where the function $\tilde{F}'_{\mu\nu} := \exp \left(\frac{i}{2} \frac{\partial}{\partial x^\mu} \frac{\partial}{\partial p_\mu} \right) \tilde{F}_{\mu\nu}$ and $\tilde{F}_{\mu\nu}$ is the Weyl-dual of the operator $\hat{F}_{\mu\nu}$, which can be obtained using (4.15).

⁸In general, the product $\hat{A}\hat{B}$ of two ordered operators \hat{A} and \hat{B} is not ordered. Nonetheless the operator algebra still closes since this product can be rewritten as a sum of correctly ordered terms. The sum of terms correspond to the various commutators one picks up through reordering \hat{x} 's and \hat{p} 's.

⁹We thank C. Zachos for pointing out an error in the expression (4.16) in an earlier version of the paper.

The formal similarity with Yang-Mills theory found thus far might lead one to expect that the field equation (4.7) follows as the Euler-Lagrange equation for (4.19). Indeed, varying the action (4.19) gives $\text{Tr} \left((\delta \hat{A}^\nu) [\hat{D}^\mu, \hat{F}_{\mu\nu}] \right)$ which would seem to suggest the equation of motion (4.7). This is not the case however. The obstruction is due to the fact that the trace Tr does not act diagonally on the components of general operator products. More will be said about this subtlety in subsection 4.2.2. We just conclude by noting that the Euler-Lagrange equation for (4.19) consists of a particular linear combination of all the components of $[\hat{D}^\mu, \hat{F}_{\mu\nu}]$. It is therefore less restrictive than (4.7) in the sense that solutions of (4.7) are also solutions of this field equation though the converse statement is not necessarily true. It may be possible to obtain (4.7) from (4.19) via additional constraints but we will not explore this further here.

4.2.1 Wigner basis for integrable functions

We will now briefly describe a particular basis for a class of classical functions which have finite integrals over phase space (a more detailed review of this construction is given in [31]). This will show us how to restrict to the class of Weyl-dual operators for which the trace map Tr is well-defined. Of course, this is necessary so that the gauge-invariant action (4.19) exists.

Consider a complete orthonormal basis of eigenfunctions $\{\psi_a\}$ for a given hamiltonian H . To each such eigenfunction $\psi_a(x)$ on \mathbb{R}^D , there is an associated *Wigner function*

$$f_a(x, p) = \frac{1}{(2\pi)^D} \int dy \psi_a^*(x - y) e^{-iy^\mu p_\mu} \psi_a(x), \quad (4.20)$$

on phase space.

One can show that such Wigner functions satisfy the orthogonality relation $f_a(x, p) \star f_b(x, p) = (1/2\pi)^D \delta_{ab} f_b(x, p)$ with respect to the \star -product (following from the fact that the eigenfunctions are orthonormal with respect to the $L^2(\mathbb{R}^D)$ inner product). Consequently the set of Wigner functions $\{f_a\}$ is closed with respect to \star multiplication. One can also show that (4.20) implies that each Wigner function is integrable over phase space since $\int dx dp f_a(x, p) = 1$ (this follows from the fact the eigenfunctions are $L^2(\mathbb{R}^D)$ normalised).

Clearly linear combinations of these Wigner functions form a vector space with a closed \star -product and admit partial derivatives which obey the Leibnitz rule. Moreover, any phase space function \tilde{A} which has an expansion in terms of Wigner functions, such that $\tilde{A}(x, p) = \sum_a \tilde{A}_a f_a(x, p)$, is guaranteed to be integrable over phase space provided the set of constant coefficients $\{\tilde{A}_a\}$ have a finite sum $\sum_a \tilde{A}_a < \infty$. Thus if we restrict to classical functions which can be expanded in this way then the corresponding Weyl-dual operators (obtained from (4.12)) will have finite traces. Imposing these restrictions guarantees the gauge-invariant action (4.19) is well-defined.

An explicit realisation of the Wigner basis defined above that would be suitable for our purposes follows from the hamiltonian $H = (p_\mu p^\mu + x^\mu x_\mu)/2$ (in euclidean signature \mathbb{R}^D) corresponding to D decoupled harmonic oscillators. The Wigner functions f_a are then each proportional to $\left[\exp \left(\frac{-i}{2} \frac{\partial}{\partial x^\mu} \frac{\partial}{\partial p_\mu} \right) (e^{-2H} L_a(4H)) \right]$, where $\{L_a | a \in \mathbb{Z}_+\}$ are the Laguerre polynomial functions. Each of these Wigner functions has Gaussian decay at

large x and p . This structure is appealing from the point of view of constructing convergent integrals though it must be understood that considering only functions of this nature on $T^*\mathbb{R}^D$ is quite a severe restriction. In particular, the set of such integrable functions on the classical phase space \mathbb{R}^{2D} is roughly as large as the set of *all* functions on \mathbb{R}^D , since the basis of the former set is in one-to-one correspondence with complete set of eigenfunctions of the hamiltonian for a particle moving on \mathbb{R}^D . In this sense, the corresponding Weyl-dual space of finite trace operators is much smaller than the complete set of functions on $T^*\mathbb{R}^D$. Consequently the number of degrees of freedom is more apt to describe a theory living on \mathbb{R}^D , with the use of $T^*\mathbb{R}^D$ viewed as a tool which allows generalisation to the non-associative theory. We expect other ways to construct finite trace operators exist wherein, for example, delta-normalisable functions like e^{ikx} would be permitted. In particular, it is conceivable that there exists a much larger space of finite trace operators that would capture more of the structure of a gauge theory on $T^*\mathbb{R}^D$.

4.2.2 Action in position space

The gauge-invariant action (4.19) was expressed as an integral over phase space. To understand the physical properties of the extended theory it would be desirable to see how this action looks as an integral over spacetime only. Such an expression can be obtained as follows. Using (4.15) allows us to express (4.19) as

$$\begin{aligned}
 & -\frac{1}{4(2\pi)^{4D}} \int dx dp dy dq dy' dq' \exp\left(-\frac{i}{2}(y^\mu q_\mu + y'^\mu q'_\mu)\right) \times \\
 & \quad \times \text{Tr}\left(\exp(-i q_\mu(\hat{x}^\mu - x^\mu)) \hat{F}_{\alpha\beta} \exp(-i y^\mu(\hat{p}_\mu - p_\mu))\right) \times \\
 & \quad \times \text{Tr}\left(\exp(-i q'_\mu(\hat{x}^\mu - x^\mu)) \hat{F}^{\alpha\beta} \exp(-i y'^\mu(\hat{p}_\mu - p_\mu))\right) \\
 & = -\frac{1}{4(2\pi)^{2D}} \int dy dq \exp(-i y^\mu q_\mu) \text{Tr}\left(\exp(-i q_\mu \hat{x}^\mu) \hat{F}_{\alpha\beta} \exp(-i y^\mu \hat{p}_\mu)\right) \times \\
 & \quad \times \text{Tr}\left(\exp(i q_\mu \hat{x}^\mu) \hat{F}^{\alpha\beta} \exp(i y^\mu \hat{p}_\mu)\right) \\
 & = -\frac{1}{4(2\pi)^D} \int dy dx dx' \delta(x - x' + y) \langle x | \hat{F}_{\alpha\beta} \exp(-i y^\mu \hat{p}_\mu) | x \rangle \langle x' | \hat{F}^{\alpha\beta} \exp(i y^\mu \hat{p}_\mu) | x' \rangle \\
 & = -\frac{1}{4(2\pi)^D} \int dy dx \langle x | \hat{F}_{\alpha\beta} \exp(-i y^\mu \hat{p}_\mu) | x \rangle \langle x + y | \hat{F}^{\alpha\beta} \exp(i y^\mu \hat{p}_\mu) | x + y \rangle. \quad (4.21)
 \end{aligned}$$

In the second line of (4.21) we have performed the x and p integrals to obtain delta functions $\delta(y + y')$ and $\delta(q + q')$ which have then been integrated. The third line of (4.21) follows by introducing a position basis $|x\rangle$ for the traces, on which $\hat{x}^\mu |x\rangle = x^\mu |x\rangle$ and $\hat{p}_\mu |x\rangle = -i\partial_\mu |x\rangle$.

Given the operator expansion (of the form (4.11)) for $\hat{F}_{\mu\nu}$ then one can formally evaluate (4.21) in terms of the coefficient functions $F_{\mu\nu}^{\alpha_1 \dots \alpha_s}$ by writing $i\hat{p}_\alpha e^{iy^\mu \hat{p}_\mu} = \partial(e^{iy^\mu \hat{p}_\mu})/\partial y^\alpha$. The action (4.21) is then proportional to

$$\sum_{s,t=0}^{\infty} \frac{(-1)^{s+t}}{s!t!} \sum_{k=0}^t \binom{t}{k} K_{\alpha_1 \dots \alpha_s \beta_{k+1} \dots \beta_t} \int dx F_{\mu\nu}^{\alpha_1 \dots \alpha_s}(x) \partial_{\beta_1} \dots \partial_{\beta_k} F^{\mu\nu \beta_1 \dots \beta_t}(x), \quad (4.22)$$

where $K_{\alpha_1 \dots \alpha_s \beta_{k+1} \dots \beta_t}$ are “volume factors”

$$\left[\frac{\partial}{\partial y^{\alpha_1}} \dots \frac{\partial}{\partial y^{\alpha_s}} \frac{\partial}{\partial y^{\beta_{k+1}}} \dots \frac{\partial}{\partial y^{\beta_t}} \delta(y) \right]_{y=0}, \quad (4.23)$$

that are constant totally symmetric tensors which weight each term in the sum (4.22). Since the delta function is a symmetric function then only the even rank tensor volume factors are non-zero and are proportional to (totally symmetrised) tensor products of the flat metric $\eta_{\mu\nu}$. Despite the obvious divergence of each of these weights, provided we restrict to the Wigner basis of integrable functions described in the previous section then the overall sum (4.22) is guaranteed to be finite. This statement is consistent with the fact that the volume factors are different for each term in the sum (4.22), so that one cannot simply redefine the action by an overall infinite scale to remove the individual divergent terms (e.g. $\delta''(0)/\delta(0)$ is still infinite).

The action (4.22) can be expressed as a finite sum of finite terms by regulating the distributions in (4.23). We achieve this by introducing an ultraviolet cutoff N in the momentum integrals defining the delta function. In particular, we define the function δ_N on euclidean \mathbb{R}^D such that

$$\delta_N(x) := \left(\frac{N}{\sqrt{2\pi}} \right)^D \exp \left(-\frac{N^2 x^2}{2} \right). \quad (4.24)$$

This corresponds to a standard representation of the Dirac delta function in the $N \rightarrow \infty$ limit (but also satisfies $\int dx \delta_N(x) = 1$ for any finite N). At the origin $\delta_N(0) = (N/\sqrt{2\pi})^D$. The regulated even rank volume factors in (4.23) can then be written

$$\partial_{\mu_1} \dots \partial_{\mu_{2r}} \delta_N(0) = (-1)^r \frac{(2r)!}{2^r r!} N^{2r} \eta_{(\mu_1 \mu_2} \dots \eta_{\mu_{2r-1} \mu_{2r})} \delta_N(0), \quad (4.25)$$

whilst the odd rank factors indeed vanish identically. This is useful because it allows one to formally factor out the delta function at the origin in (4.22) to obtain the regulated action

$$\begin{aligned} \delta_N(0) \sum_{s,t=0}^{\infty} \frac{1}{s!t!} \sum_{k=0}^t \binom{t}{k} (-1)^{\frac{s+t+k}{2}} \frac{(s+t-k)!}{2^{\frac{s+t-k}{2}} \left(\frac{s+t-k}{2}\right)!} N^{s+t-k} \times \\ \times \int dx F_{\mu\nu}^{\alpha_1 \dots \alpha_s} \partial_{\beta_1} \dots \partial_{\beta_k} F^{\mu\nu \beta_1 \dots \beta_t} \eta_{(\alpha_1 \alpha_2} \dots \eta_{\alpha_s \beta_{k+1}} \dots \eta_{\beta_{t-1} \beta_t)}, \end{aligned} \quad (4.26)$$

where the sums are over all terms with $s+t-k$ even. A finite action in position space will be obtained from (4.26) in the $N \rightarrow \infty$ limit where the cutoff is removed following a simple field redefinition that will be described in section 4.3.

The expression above illustrates the point made about the non-diagonal action of the trace on operator products at the end of section 4.2. That is, the total symmetrisation of all the metric indices above implies that, even in the $k=0$ sum, one does not have only diagonal terms of the form $F_{\mu\nu\alpha_1 \dots \alpha_s} F^{\mu\nu\alpha_1 \dots \alpha_s}$ in the lagrangian. Off-diagonal terms involving traces of individual field strength component indices, like $F_{\mu\nu\alpha_1 \dots \alpha_s}^{\alpha} F^{\mu\nu\alpha_1 \dots \alpha_s}$, are also present. This property is clearly independent of having introduced the cutoff and would indeed occur when formally evaluating (4.22).

4.3 The extended theory in component form

To investigate the connection with interacting higher spin gauge theory, it will now be enlightening to examine in more detail some of the features of the extended theory in component form.

The components of the gauge field \hat{A}_μ transform infinitesimally as

$$\begin{aligned}\delta A_\mu^{\alpha_1 \cdots \alpha_s} &= -\partial_\mu \epsilon^{\alpha_1 \cdots \alpha_s} + \hat{E}^{\alpha_1 \cdots \alpha_s}(\hat{A}_\mu, \hat{\epsilon}) \\ &= -\partial_\mu \epsilon^{\alpha_1 \cdots \alpha_s} + \sum_{k=0}^s \binom{s}{k} \sum_{r=1}^{\infty} \frac{1}{r!} \left\{ \left(\partial_{\beta_1} \cdots \partial_{\beta_r} A_\mu^{(\alpha_1 \cdots \alpha_k)} \right) \epsilon^{\alpha_{k+1} \cdots \alpha_s} \beta_1 \cdots \beta_r - \right. \\ &\quad \left. - \left(\partial_{\beta_1} \cdots \partial_{\beta_r} \epsilon^{(\alpha_1 \cdots \alpha_k)} \right) A_\mu^{\alpha_{k+1} \cdots \alpha_s} \beta_1 \cdots \beta_r \right\}, \quad (4.27)\end{aligned}$$

under (4.3). The second line of (4.27) follows from equation (A.5) proven in appendix A.

The components of the field strength $\hat{F}_{\mu\nu}$ (4.5) are functions which can be written in terms of the components of \hat{A}_μ as

$$\begin{aligned}F_{\mu\nu}^{\alpha_1 \cdots \alpha_s} &= 2\partial_{[\mu} A_{\nu]}^{\alpha_1 \cdots \alpha_s} - \hat{E}^{\alpha_1 \cdots \alpha_s}(\hat{A}_\mu, \hat{A}_\nu) \\ &= 2\partial_{[\mu} A_{\nu]}^{\alpha_1 \cdots \alpha_s} - \sum_{k=0}^s \binom{s}{k} \sum_{r=1}^{\infty} \frac{1}{r!} \left\{ \left(\partial_{\beta_1} \cdots \partial_{\beta_r} A_\mu^{(\alpha_1 \cdots \alpha_k)} \right) A_\nu^{\alpha_{k+1} \cdots \alpha_s} \beta_1 \cdots \beta_r - \right. \\ &\quad \left. - \left(\partial_{\beta_1} \cdots \partial_{\beta_r} A_\nu^{(\alpha_1 \cdots \alpha_k)} \right) A_\mu^{\alpha_{k+1} \cdots \alpha_s} \beta_1 \cdots \beta_r \right\}, \quad (4.28)\end{aligned}$$

where (square) bracketed indices are (anti)symmetrised with weight 1. By construction, the functions $F_{\mu\nu}^{\alpha_1 \cdots \alpha_s}$ transform in the $(GL(D, \mathbb{R})\text{-reducible})$ tensor product representation corresponding to a two-form times a totally symmetric rank- s tensor of the Lorentz group (written $(1, 1) \otimes (s)^{10}$).

The non-linear terms in the field strength components above imply that the gauge-invariant action (4.26) is not conformally-invariant. Since the momentum cutoff N has length dimension -1 then the action (4.26) is only dimensionless provided the field strength component $F_{\mu\nu}^{\alpha_1 \cdots \alpha_s}$ in (4.28) has length dimension s (coordinates x^μ have dimension 1 and metric components $\eta_{\mu\nu}$ are dimensionless). One must then introduce dimensionful coupling constants to ensure that the linear and non-linear gauge field terms in (4.28) have the same dimension. If one considers the linear part of the field strength (4.28) only then the action (4.26) would be scale invariant provided each gauge field $A_\mu^{\alpha_1 \cdots \alpha_s}$ has length dimension $s + 1$. A non-linear term in (4.28) must then have length dimension $s + 2$. The associated coupling constant g must therefore have dimension -2 for any value of s . Dimensional consistency thus requires a factor of g to multiply the non-linear terms in both (4.27) and (4.28). Since the action (4.26) is quadratic in the field strength components (4.28) then, in addition to the kinetic terms that are quadratic in the gauge fields, there are both cubic and quartic interaction terms with couplings g and g^2 respectively. This structure is just as in standard Yang-Mills theory.

¹⁰We take (p_1, \dots, p_k) to denote the $GL(D, \mathbb{R})$ -irreducible representation corresponding to a Young tableau with k rows, each of length p_i (where $i = 1, \dots, k$).

The cutoff dependence of the $k = 0$ terms in (4.26) can be formally removed by a simple redefinition $F_{\mu\nu}^{\alpha_1 \dots \alpha_s} \rightarrow N^{-s-D/2} F_{\mu\nu}^{\alpha_1 \dots \alpha_s}$ of each of the field strength components (4.28). The redefined action is then proportional to

$$\sum_{s=0}^{\infty} \sum_{t \leq s} \frac{(-1)^s (2s)!}{(s+t)!(s-t)!2^s s!} \int dx F_{\mu\nu}^{\alpha_1 \dots \alpha_{s+t}} F^{\mu\nu \alpha_{s+t+1} \dots \alpha_{2s}} \eta_{(\alpha_1 \alpha_2} \dots \eta_{\alpha_{2s-1} \alpha_{2s})}, \quad (4.29)$$

up to the addition of $k > 0$ terms involving only inverse powers of N that will vanish in the $N \rightarrow \infty$ limit when the cutoff is removed.

Since N is dimensionful, the redefinition modifies the dimensions of each gauge field and coupling in the action. In particular, the redefinition of the field strength above follows from the redefinition $A_{\mu}^{\alpha_1 \dots \alpha_s} \rightarrow N^{-s-D/2} A_{\mu}^{\alpha_1 \dots \alpha_s}$ (hence each $A_{\mu}^{\alpha_1 \dots \alpha_s}$ now has dimension $1 - D/2$). The effect of this redefinition in the gauge transformation (4.27) and field strength (4.28) is to modify the coupling constants multiplying the non-linear terms. For every s , a non-linear term of fixed r in (4.27) and (4.28) has the coupling g mentioned above replaced by $g_{(r)} := N^{-r-D/2} g$. The coupling $g_{(r)}$ has dimension $r - 2 + D/2$, which is always positive for $D > 2$. Notice that, if g is a fixed finite number, all the couplings $g_{(r)}$ vanish in the limit $N \rightarrow \infty$. The single coupling constant $g_{(1)}$ can be kept finite and non-zero as $N \rightarrow \infty$, by choosing g to scale like $N^{1+D/2} g_f$ in this limit (for some finite parameter g_f). The free theory can then be obtained by setting $g_{(1)} = g_f = 0$. For small g_f , the interacting theory could be quantised as a perturbation of this free limit.

Coupling constants with positive spin-dependent length dimensions, such as discussed above, have also been found for interacting higher spin theories in flat space in the earlier work [11]. The couplings $g_{(r)}$ are similar in structure to the 't Hooft parameters discussed in the context of holography for general brane solutions of string theory in [12]. This is because the cutoff N we have introduced to regulate the delta functions is related to the number of degrees of freedom of the extended theory. It would be interesting to understand whether these couplings are also indicative of a holographic interpretation for the extended theory we have described.

4.3.1 Higher spin symmetry

By construction, the field strength components (4.28) transform in the appropriate covariant sense under (4.27). Indeed if we restrict attention to the linear terms in these formulas then it is clear that $F_{\mu\nu\alpha_1 \dots \alpha_s} = 2\partial_{[\mu} A_{\nu]\alpha_1 \dots \alpha_s}$ is invariant under $\delta A_{\mu\alpha_1 \dots \alpha_s} = -\partial_{\mu} \epsilon_{\alpha_1 \dots \alpha_s}$. However, as explained in [7], the most general first order infinitesimal transformation for a linear gauge field in the representation $(1) \otimes (s)$ of the Lorentz group is

$$\delta A_{\mu\alpha_1 \dots \alpha_s} = \partial_{\mu} \varepsilon_{\alpha_1 \dots \alpha_s} + s \partial_{(\alpha_1} \xi_{\alpha_2 \dots \alpha_s) \mu}, \quad (4.30)$$

in terms of the rank- s tensor parameters $\varepsilon_{\alpha_1 \dots \alpha_s}$ (in the totally symmetric (s) representation) and $\xi_{\alpha_1 \dots \alpha_{s-1} \mu}$ (in the $GL(D, \mathbb{R})$ -reducible $(1) \otimes (s-1)$ representation). The corresponding linear field strength that is invariant under (4.30) involves $s+1$ derivatives of $A_{\mu\alpha_1 \dots \alpha_s}$ and is given by

$$2^{s+1} \partial_{[\alpha_1} \dots \partial_{\alpha_s} \partial_{[\mu} A_{\nu] \beta_s] \dots \beta_1]}. \quad (4.31)$$

The various sets of square brackets indicate antisymmetrisation of the $s + 1$ pairs of indices $[\mu\nu]$, $[\alpha_1\beta_1]$, \dots , $[\alpha_s\beta_s]$ separately. It is therefore important to understand that the extended theory (as we have described it) does not realise all the possible gauge symmetries even at the linear level. That is we have effectively taken $\varepsilon = -\epsilon$ and $\xi = 0$ in (4.30) and so were able to realise a gauge-invariant field strength involving only one derivative of $A_{\mu\alpha_1\dots\alpha_s}$. A consequence of this fact is that one has not enough gauge symmetry to fix all the components of the higher spin fields that could give rise to states of negative norm in the quantum theory in lorentzian signature. This is not an issue in euclidean \mathbb{R}^D . The interpretation of the extended theory in euclidean signature will be discussed in section 5.2.

4.3.2 Gauge-fixing in lorentzian signature

Let us briefly review how a gauge-fixing of the theory in lorentzian signature could be achieved at the linear level, given the full symmetry (4.30). For simplicity, let us first focus on the $s = 1$ component $A_{\mu\alpha}$ in (4.30). There are exactly $2D - 1$ temporal components A_{0a} , A_{m0} and A_{00} of this field that lead to non-unitarity (since they obstruct $A_{\mu\alpha}$ being transverse to the timelike/null direction defining the massive/massless little group of $\text{SO}(D - 1, 1)$). There are $2D$ gauge parameters ε_α and ξ_μ which contain $2D - 2$ spacelike components ε_a and ξ_m that can be used to gauge away the components A_{0a} and A_{m0} . One of the two timelike gauge parameter components (ε_0 or ξ_0) is itself removed via the residual $\delta\varepsilon_\alpha = \partial_\alpha\lambda$, $\delta\xi_\mu = -\partial_\mu\lambda$ symmetry in (4.30). The remaining timelike component can then be used to gauge away A_{00} . As discussed in [7], this can be done in a Lorentz-covariant way via a specific gauge-fixing procedure, resulting in the on-shell constraints $\partial^\mu A_{\mu\alpha} = 0$, $\partial^\alpha A_{\mu\alpha} = 0$ and $A^\mu_\mu = 0$ on the gauge field. The analysis above can be repeated for the general higher spin field $A_{\mu\alpha_1\dots\alpha_s}$ and one again finds that all the temporal components of this gauge field can be removed using the gauge parameters $\varepsilon_{\alpha_1\dots\alpha_s}$ and $\xi_{\alpha_1\dots\alpha_{s-1}\mu}$. In terms of counting this can be easily seen from the fact that all the time-like components of $A_{\mu\alpha_1\dots\alpha_s}$ can be written as $A_{0\alpha_1\dots\alpha_s}$ and $A_{\mu 0\alpha_1\dots\alpha_{s-1}}$, which are in the same representations of the Lorentz group as the gauge parameters $\varepsilon_{\alpha_1\dots\alpha_s}$ and $\xi_{\alpha_1\dots\alpha_{s-1}\mu}$ respectively. Of course, $A_{0\alpha_1\dots\alpha_s}$ and $A_{\mu 0\alpha_1\dots\alpha_{s-1}}$ have the temporal elements $A_{00\alpha_1\dots\alpha_{s-1}}$ in common and so it would seem there are $\binom{D+s-2}{s-1}$ more gauge parameters than temporal components of the gauge field. However, the residual symmetries $\delta\varepsilon_{\alpha_1\dots\alpha_s} = s\partial_{(\alpha_1}\lambda_{\alpha_2\dots\alpha_s)}$, $\delta\xi_{\alpha_1\dots\alpha_{s-1}\mu} = -\partial_\mu\lambda_{\alpha_1\dots\alpha_{s-1}}$ of the gauge parameters in (4.30) mean that precisely the $\binom{D+s-2}{s-1}$ unaccounted for parameters can be gauged away, thus making the counting correct. This gauge-fixing can be performed covariantly to yield the on-shell constraints $\partial^\mu A_{\mu\alpha_1\dots\alpha_s} = 0$, $\partial^\alpha A_{\mu\alpha_1\dots\alpha_{s-1}} = 0$, $A^\mu_{\mu\alpha_1\dots\alpha_{s-1}} = 0$ and $A^\alpha_{\mu\alpha_1\dots\alpha_{s-2}} = 0$, for each $A_{\mu\alpha_1\dots\alpha_s}$.

A unitary version of the extended theory we have described would require sufficient constraints on $A_{\mu\alpha_1\dots\alpha_s}$ and $\epsilon_{\alpha_1\dots\alpha_s}$ to compensate for the lack of $\xi_{\alpha_1\dots\alpha_{s-1}\mu}$ symmetry. One obvious way this could be achieved would be to define the “partially gauge-fixed” path integral as a sum over the $A_{\mu a_1\dots a_s}$ and $\epsilon_{a_1\dots a_s}$ components only (that is where the “gauge” indices α are purely spacelike). Clearly the gauge symmetry $\epsilon_{a_1\dots a_s}$ is sufficient to fix the non-vanishing timelike components $A_{0a_1\dots a_s}$ of the higher spin fields. In the linear theory, such a gauge can be imposed in a Lorentz-covariant manner via the constraints $\partial^\alpha A_{\mu\alpha_1\dots\alpha_{s-1}} = 0$, $A^\mu_{\mu\alpha_1\dots\alpha_{s-1}} = 0$ and $A^\alpha_{\mu\alpha_1\dots\alpha_{s-2}} = 0$, which are invariant under gauge

transformations with parameter satisfying $\partial^\alpha \epsilon_{\alpha\alpha_1\cdots\alpha_{s-1}} = 0$ and $\epsilon_{\alpha\alpha_1\cdots\alpha_{s-2}}^\alpha = 0$. The constraint $\partial^\mu A_{\mu\alpha_1\cdots\alpha_s} = 0$, however, only follows after fixing the remaining (harmonic part of the) $\epsilon_{a_1\cdots a_s}$ symmetry. It is not clear though whether there exist appropriate generalisations of the Lorentz-covariant constraints above for the non-linear theory. As for massive gauge theories, it is possible that the symmetry broken by interactions in the extended theory implies that such constraints follow as identities from the equation of motion (4.7).

4.3.3 Comments on restoring full gauge symmetry

Since the extended theory has a Yang-Mills type structure on $T^*\mathbb{R}^D$ then it is not surprising that it does not realise all the higher spin symmetries. This is simply because of the $U(1)$ principal bundle structure over $T^*\mathbb{R}^D$ we are implicitly using. The connection on this bundle is just given by the covariant derivative \hat{D}_μ (4.4) and so the curvature $\hat{F}_{\mu\nu} = [\hat{D}_\mu, \hat{D}_\nu]$ naturally contains a linear term involving only one derivative of the higher spin fields. As already noted above, even at the linear level one requires a higher derivative field strength (4.31) to realise all the higher spin symmetries. Of course, if a fully gauge-invariant formulation of the extended theory exists then one might expect there to exist some generalised covariant derivative that would replace partial derivatives in (4.30) and (4.31) (followed by appropriate Young symmetrisation if necessary). Such a generalised covariant derivative cannot simply be \hat{D}_μ since, by construction, this only transforms covariantly under the $\epsilon_{\alpha_1\cdots\alpha_s}$ part of the higher spin symmetry. All that can be said is that it must reduce to \hat{D}_μ in the “partially broken” phase of the theory we have described.

Such a partially broken structure would perhaps be similar to what happens for free higher spin theories where the Fronsdal equations [13] for totally symmetric tensor gauge fields (which are second order in derivatives) are not invariant under the most general gauge transformation for such fields. In particular one finds that the trace part of the gauge parameter cannot be realised as a symmetry of the equations of motion and so is set to zero. To construct an action realising this traceless gauge symmetry one must then impose the constraint that the double trace of the higher spin field vanishes. It is now known that these Fronsdal equations can be reobtained from the fully gauge-invariant (but non-local) field equations given in [17, 7]. One can also realise the trace part of the gauge symmetry by reintroducing the double trace part of the field as a compensator field which restores the full gauge symmetry in the Fronsdal formalism [13]. A fully gauge-invariant reformulation of the extended theory may therefore require additional compensator fields. More will be said about this point in section 5.2.

4.4 Comparison with Vasiliev theory

The non-linearities in (4.27) and (4.28) suggest that the action and field equations found earlier describe interactions between the infinite number of component higher spin gauge fields $A_\mu^{\alpha_1\cdots\alpha_s}$. As we have seen, even at the free level, the formulation of higher spin gauge theories is a rather subtle problem (and is discussed, for example in [7]–[10], [13]–[17]). Perhaps not surprisingly, the formulation of gauge-invariant interacting higher spin theories is even more complicated. Attempts to construct such models in flat space have been considered in [11, 32, 33]. The only known consistent framework to describe interacting

higher spin gauge theories was developed by Vasiliev [18], [19] (see also [21]). We now give a brief summary of this construction [20] in order to compare the structure with that of (the associative limit of) the extended theory we have described above.

The approach is based on an extension of the MacDowell-Mansouri formulation of anti-de Sitter gravity [34]. Recall that the frame-like formulation of gravity can be considered as a gauging of the Poincaré group $SO(D-1, 1) \ltimes \mathbb{R}^D$. The gauge fields related to translations and rotations are the vielbein e_μ^α and the Lorentz connection $\omega_\mu^{\alpha\beta} = -\omega_\mu^{\beta\alpha}$ respectively. The curvature for the vielbein and Lorentz connection are respectively proportional to the torsion and Riemann tensors of the spacetime geometry. Setting the torsion to zero then allows one to solve for the Lorentz connection in terms of the vielbein in the usual way. The MacDowell-Mansouri idea was to instead gauge the AdS_D isometry group $SO(D-1, 2)$. The gauge field associated with $SO(D-1, 2)$ rotations is written $\omega_\mu^{AB} = -\omega_\mu^{BA}$. If one fixes a timelike vector in the auxiliary space \mathbb{R}^{D+1} then this gauge field can be decomposed into e_μ^α and $\omega_\mu^{\alpha\beta}$ (with gauge indices transverse to the fixed timelike direction). This reduced theory does not quite correspond to the gauging of the Poincaré group described above though since the “translation” generators fail to commute with each other up to an $SO(D-1, 1)$ rotation with coefficient proportional to the inverse norm-squared of the fixed timelike vector in the auxiliary space. In fact the reduced theory precisely describes gravity on AdS_D (i.e. in the presence of a cosmological constant which is identified with the aforementioned coefficient in the algebra). A particularly nice feature of this construction is that it allows one to express the Einstein-Hilbert lagrangian (with cosmological term) in a manifestly $SO(D-1, 2)$ -invariant form, in terms of the curvature of the connection ω_μ^{AB} and the fixed timelike vector in the auxiliary space only.

Vasiliev considers an extended version of this formulation of gravity on AdS_D in terms of an infinite set of fields $\{\omega_\mu^{A_1 \dots A_s B_1 \dots B_s} | s \geq 0\}$. The gauge indices for a given field here transform in the traceless (s, s) irreducible representation of the anti-de Sitter group $SO(D-1, 2)$ (i.e. they correspond to Young tableau with two rows of equal length). Just as in the MacDowell-Mansouri formulation of gravity, one can fix a timelike vector in the auxiliary space (whose norm is again related to the cosmological constant) and decompose the fields above in representations of $SO(D-1, 1)$. This results in the set of generalised vielbeins $\{e_\mu^{\alpha_1 \dots \alpha_s} | s \geq 0\}$ and Lorentz connections $\{\omega_\mu^{\alpha_1 \dots \alpha_s \beta_1 \dots \beta_t} | 0 < t \leq s, s \geq 0\}$. The underlying infinite-dimensional extension of the anti-de Sitter algebra that determines the non-linear terms in the curvature for this gauging is called $hu(1|sp(2)[D-1, 2])$ and has also been found as an extension of the conformal algebra in $D-1$ dimensions by Eastwood [35] in considering all possible symmetries of the Laplace equation for a scalar field on \mathbb{R}^{D-1} . The details of this rather complicated algebra need not concern us here, sufficed to say that its maximal finite-dimensional subalgebra is $so(D-1, 2)$.

The precise form of the non-linear interaction terms involving all the component fields also becomes very complicated. To simplify matters one can perform a linearised analysis around a fixed anti-de Sitter background. The gauge-invariant action for this free theory can be written in a MacDowell-Mansouri form in terms of the linearised curva-

ture for $\omega_\mu^{A_1 \dots A_s B_1 \dots B_s}$ and the fixed timelike vector only. More precisely, it is a sum of MacDowell-Mansouri type actions with relative coefficients fixed such that the only non-trivial variations come from the gauge transformations of the fields $e_\mu^{\alpha_1 \dots \alpha_s}$ and $\omega_\mu^{\alpha_1 \dots \alpha_s \beta}$. The gauge parameters for these fields are written $\varepsilon^{\alpha_1 \dots \alpha_s}$ and $\xi^{\alpha_1 \dots \alpha_s \beta}$ respectively (and can be understood as generalisations of linearised diffeomorphisms and local Lorentz transformations). A generalisation of the “no torsion” constraint further implies that all $\omega_\mu^{\alpha_1 \dots \alpha_s \beta}$ can be solved in terms of (first derivatives of) the fields $e_\mu^{\alpha_1 \dots \alpha_s}$. Consequently, each remaining $\xi^{\alpha_1 \dots \alpha_s \beta}$ symmetry can be used to gauge away the “hook” part of $e_{\beta\alpha_1 \dots \alpha_s}$.¹¹ The resulting action is then simply an infinite sum of Fronsdaal actions [13] for all possible free totally symmetric fields $e_{(\mu\alpha_1 \dots \alpha_s)}$ on AdS_D . Since $e_{\mu\alpha}^{\alpha\alpha_2 \dots \alpha_s} = 0$ then the symmetric parts $e_{(\mu\alpha_1 \dots \alpha_s)}$ obey the double tracelessness constraint in [13].

Despite the fact that we have considered a flat rather than anti-de Sitter background, it is still tempting to naively identify the components of the extended gauge field $A_\mu^{\alpha_1 \dots \alpha_s}$ with the generalised vielbeins $e_\mu^{\alpha_1 \dots \alpha_s}$ in the Vasiliev theory. The similarity between these fields does not seem to extend much beyond their index structure though. Even at this level there are some subtle differences. In particular, gauge-invariance in the Vasiliev theory requires the trace constraint $e_{\mu\alpha}^{\alpha\alpha_2 \dots \alpha_s} = 0$, which is not necessary in the extended theory. As discussed in subsection 4.3.2, this constraint seems to be related to unitarity in the extended theory. We therefore do not exclude the possibility that a fully gauge-invariant formulation of the extended theory could be related more closely to Vasiliev theory. We will not investigate this possibility further here though since many of the spacetime geometrical concepts in the Vasiliev theory (e.g. the generalised Lorentz connections) have no obvious analogue from the gauge theory perspective.

At the level we have described it, it is not even clear whether the extended theory contains gravity. Indeed naively setting all the component higher spin fields (and gauge parameters) except the vielbein-like field A_μ^α (and parameter ϵ^α) to zero does not reproduce the frame-like formulation of gravity (that one would obtain by doing this for the Vasiliev theory). In particular, the only non-trivial parts of the gauge transformation (4.27) and field strength (4.28) then become $\delta A_\mu^\alpha = -\partial_\mu \epsilon^\alpha + (\partial_\beta A_\mu^\alpha) \epsilon^\beta - (\partial_\beta \epsilon^\alpha) A_\mu^\beta$ and $F_{\mu\nu}^\alpha = 2\partial_{[\mu} A_{\nu]}^\alpha - 2(\partial_\beta A_{[\mu}^\alpha) A_{\nu]}^\beta$. This gauge transformation and field strength would correspond to vielbein diffeomorphism and torsion tensor in the naive correspondence with gravity. These quantities clearly do not have the form necessary for this correspondence to be true¹² (except maybe in the presence of additional constraints).

These differences should perhaps be expected since our description was considered as an extension of Maxwell theory which, of course, has a local $U(1)$ gauge symmetry and a global Poincaré spacetime symmetry. The Vasiliev theory follows from a similar extension but of gravity on AdS_D with local $SO(D-1, 2)$ spacetime symmetry. Thus, just as Vasiliev theory naturally contains anti-de Sitter gravity, we should expect that there exists some consistent way to embed Maxwell theory in our extended formalism.

¹¹That is, the piece of $e_{\beta\alpha_1 \dots \alpha_s}$ which is not totally symmetric and so transforms in the $(s, 1)$ representation of the local Lorentz group. This is simply the generalisation of the antisymmetric part of the vielbein being removed by local Lorentz symmetry to give the graviton.

¹²For example, unlike the vielbein, the field A_μ^α is not even required to be an invertible matrix.

4.5 Abelian embedding

A similarity between Vasiliev's formulation of higher spin gauge theory and the associative limit of the extended theory can be seen in the way one embeds a simple abelian gauge theory in the latter which just follows the *unfolding* procedure for the former. In particular, notice that all the non-linear terms in (4.27) and (4.28) vanish if we take the extended gauge field \hat{A}_μ and parameter $\hat{\epsilon}$ to have components

$$\begin{aligned} A_{\mu\alpha_1\cdots\alpha_s} &= \partial_{\alpha_1} \cdots \partial_{\alpha_s} A_\mu, \\ \epsilon_{\alpha_1\cdots\alpha_s} &= \partial_{\alpha_1} \cdots \partial_{\alpha_s} \epsilon. \end{aligned} \quad (4.32)$$

This result is proved in appendix A where it is found that operators with components of this form generate an abelian subalgebra of the commutator algebra of differential operators on \mathbb{R}^D . The constraint (4.32) relates all the higher spin components of \hat{A}_μ and $\hat{\epsilon}$ to their lowest order components A_μ and ϵ . These functions represent the Maxwell potential and parameter used in the conventional description of abelian gauge theory on \mathbb{R}^D . The higher spin $s > 0$ component gauge transformations (4.27) and field strengths (4.28) are also not independent since they just correspond to $s > 0$ derivatives of the $s = 0$ Maxwell gauge transformation $\delta A_\mu = -\partial_\mu \epsilon$ and field strength $F_{\mu\nu} = 2\partial_{[\mu} A_{\nu]}$. In a similar manner, the field equations (4.7) just reduce to the Maxwell equations $\partial^\mu F_{\mu\nu} = 0$ upon imposing (4.32). The field equations that follow from the gauge-invariant action (4.29) upon imposing (4.32) however take the form $(\sum_{s=0}^{\infty} c_s \square^s) \partial^\mu F_{\mu\nu} = 0$, where c_s are constants and $\square := \partial_\mu \partial^\mu$. As already observed for the non-linear theory, this equation is indeed less restrictive than $\partial^\mu F_{\mu\nu} = 0$. In fact, equations of this less restrictive kind were also described for more general free higher spin fields in [7].

The constraints (4.32) are a simple case of the more general principle of unfolding used by Vasiliev (see e.g. [20]) to show how a higher spin theory with an infinite number of fields can describe a finite number of physical degrees of freedom. A classic example is where one has an infinite set of independent totally symmetric traceless tensors of increasing rank $\{\phi_{\mu_1\cdots\mu_s} | s \geq 0\}$. This set simply describes a massless free scalar field ϕ if supplemented with the infinite set of constraints $\phi_{\alpha_1\cdots\alpha_s} = \partial_{\alpha_1} \cdots \partial_{\alpha_s} \phi$. It is clear that such constraints relate all the higher spin fields to the scalar ϕ . The dynamics of this scalar field are encapsulated by the tracelessness of each $\phi_{\mu_1\cdots\mu_s}$ when supplemented with the constraints. In particular, the tracelessness of the constraint $\phi_{\mu\nu} = \partial_\mu \partial_\nu \phi$ implies that ϕ satisfies the massless Klein-Gordon equation $\square \phi = 0$. This is similar to what we find for the embedding described above. In particular, if $A_{\mu\alpha_1\cdots\alpha_s}$ are traceless (for any pair of contracted indices), then the first constraints in (4.32) are equivalent to the correct Maxwell equations $\square A_\mu = 0$ and $\partial^\mu A_\mu = 0$ (in Lorentz gauge). If $\epsilon_{\alpha_1\cdots\alpha_s}$ are also traceless then the second constraints in (4.32) imply $\square \epsilon = 0$ which gives the class of harmonic gauge transformations $\delta A_\mu = -\partial_\mu \epsilon$ under which the aforementioned (gauge-fixed) Maxwell equations are invariant.

4.5.1 Symplectic transformations and abelian embedding

The construction of the ansatz (4.32) relied on the existence of an abelian subalgebra of the commutator algebra of differential operators on \mathbb{R}^D . The abelian subalgebra used in (4.32)

was the one given in appendix A. A generalisation which leads to other (less restrictive) ansatzes can be derived as follows.

Recall that the Heisenberg algebra $[\hat{x}^\mu, \hat{p}_\nu] = i\delta_\nu^\mu$ in D -dimensions is invariant under the linear action of the symplectic group $Sp(D)$. This group consists of real $2D \times 2D$ matrices M which obey $MJM^t = J$, where

$$J = \begin{pmatrix} 0 & 1_D \\ -1_D & 0 \end{pmatrix}, \quad (4.33)$$

is the canonical symplectic form. When divided into $D \times D$ blocks,

$$M = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad (4.34)$$

where a , b , c and d are real $D \times D$ constant matrices which obey $ab^t = ba^t$, $cd^t = dc^t$ and $ad^t - bc^t = 1_D$. Block triangular symplectic matrices of the form (4.34) with $c = 0$ form a subgroup of $Sp(D)$. The symplectic constraints for this subgroup are that $ab^t = (ab^t)^t$ and $d^t = a^{-1}$. The fact that ab^t is a symmetric $D \times D$ matrix for this subgroup implies that $a^{-1}b$ is also symmetric.

Consider now the canonical position space representation of this Heisenberg algebra (where \hat{x}^μ and \hat{p}_ν act as x^μ and $-i\partial_\nu$ respectively on the basis vectors $|x^\mu\rangle$ of the Hilbert space). General operators in this representation thus correspond to functions $A(x, \partial)$. If we write the operators x^μ and ∂^ν as a $2D$ -component column vector

$$X := \begin{pmatrix} x \\ \partial \end{pmatrix}, \quad (4.35)$$

then the symplectic group defined above has the simple matrix multiplication action $X \rightarrow MX$ on this representation. In terms of the D -dimensional blocks, this translates to $x \rightarrow ax + b\partial$ and $\partial \rightarrow cx + d\partial$. A class of mutually commuting operators are those which are diagonal with respect to the basis $|x^\mu\rangle$. That is, functions $H(x) := A(x, 0)$ of x^μ only in this representation. The subgroup of block triangular symplectic matrices defined above map commuting operators to commuting operators. In particular, such triangular matrices transform $x \rightarrow ax + b\partial$ and $\partial \rightarrow d\partial$, so that the function $H(x)$ is mapped to the function $H(ax + b\partial)$. All such functions $H(ax + b\partial)$ are still mutually commuting. This fact can be verified using the Taylor expansion

$$\begin{aligned} H(ax + b\partial) &= H(ax) + (\partial_\mu H(ax))(a^{-1}b\partial)^\mu + \frac{1}{2}(\partial_\mu \partial_\nu H(ax))(a^{-1}b\partial)^\mu (a^{-1}b\partial)^\nu + \dots \\ &= \sum_{s=0}^{\infty} \frac{1}{s!} (\partial_{\mu_1} \dots \partial_{\mu_s} H(ax)) (a^{-1}b)^{\mu_1 \nu_1} \dots (a^{-1}b)^{\mu_s \nu_s} \partial_{\nu_1} \dots \partial_{\nu_s}, \end{aligned} \quad (4.36)$$

together with the fact that $a^{-1}b$ is symmetric (where $(a^{-1}b\partial)^\mu \equiv (a^{-1}b)^\mu_\nu \partial^\nu$). Such commuting operators clearly correspond to a restricted class of functions on $T^*\mathbb{R}^D$ but are more general than those found in appendix A. The discussion in appendix A corresponds to operators in (4.36) with $a = b = 1_D$.

The natural generalisation of the embedding (4.32) is therefore to impose

$$\begin{aligned} A_{\mu\alpha_1\cdots\alpha_s}(x) &= (a^{-1}b)_{\alpha_1\beta_1} \cdots (a^{-1}b)_{\alpha_s\beta_s} \partial^{\beta_1} \cdots \partial^{\beta_s} A_\mu(x), \\ \epsilon_{\alpha_1\cdots\alpha_s}(x) &= (a^{-1}b)_{\alpha_1\beta_1} \cdots (a^{-1}b)_{\alpha_s\beta_s} \partial^{\beta_1} \cdots \partial^{\beta_s} \epsilon(x), \end{aligned} \quad (4.37)$$

on all the $s > 0$ components, for any constant $D \times D$ matrices a and b satisfying $a^{-1}b = (a^{-1}b)^t$ (hence a must also be invertible).¹³ Taking $a = b$ in (4.37) reproduces the embedding (4.32) whilst taking $b = 0$ in (4.37) gives the embedding proposed in [1] Since operators with components of this form commute with each other then Maxwell theory follows in the same way as was described in the previous subsection.

5. Comments and discussion

This section outlines how the theory described in section 4 is related to several constructions familiar in string theory. Various generalisations of the extended theory are also discussed. We begin by showing how the associative limit of the extended theory is equivalent to a gauge-invariant projection of a non-commutative gauge theory. We explain that consideration of the theory in euclidean signature is important from the perspective of fuzzy sphere solutions of Matrix theory. We suggest how a formulation in de Sitter space could resolve the issues regarding non-unitarity in the lorentzian theory. We then discuss how one might describe certain physical properties of the non-associative theory.

5.1 Relation to non-commutative gauge theory

We have observed that the gauge theory related to the non-associative space $\mathcal{A}_n^*(\mathbb{R}^D)$ is naturally formulated on the deformed cotangent bundle $\mathcal{A}_n^*(T^*\mathbb{R}^D)$. This extended gauge theory was found to remain non-trivial in the associative limit in section 4. In this limit there are D covariant derivatives $\hat{D}_\mu = \partial_\mu + A_\mu(x, \partial)$. The structure of gauge fields here is just as one finds for gauge theory on the $2D$ -dimensional non-commutative space $T^*\mathbb{R}^D$ (see for example [23, 40]), where the non-commutativity parameter is given by the canonical symplectic form on the cotangent bundle. One difference is that the non-commutative gauge theory on $T^*\mathbb{R}^D$ has $2D$ covariant derivatives $\hat{D}_M = \partial_M + A_M(X)$ (where $M = 1, \dots, 2D$). The $2D$ coordinates on $T^*\mathbb{R}^D$ are written $X^M = (x^\mu, x^{\tilde{\nu}}) = (-i\partial^{\tilde{\mu}}, -i\partial^\nu)$ (where $\mu, \nu = 1, \dots, D$ and $\tilde{\mu} = \mu + D = D + 1, \dots, 2D$) and obey the algebra $[X^M, X^N] = i\Theta^{MN}$ (where only $\Theta^{\mu\tilde{\nu}} = -\Theta^{\tilde{\nu}\mu} = \delta^{\mu\nu}$ are non-vanishing). The discussion can be formally developed for the lorentzian case by replacing $\delta^{\mu\nu}$ with $\eta^{\mu\nu}$, but will be more subtle since there are then two timelike directions.

A gauge field satisfying $\hat{D}_{\tilde{\mu}} = 0$ is given by $(\hat{A}_\mu, \hat{A}_{\tilde{\nu}}) = (a_\mu, -ix_\nu)$. This configuration has vanishing field strength $[\hat{D}_M, \hat{D}_N] = 0$ for any constant a_μ . It evidently solves the field equations although for actions usually considered in non-commutative gauge theory (e.g. [41]), which contain the square of a shifted field strength $[\hat{D}_M, \hat{D}_N] + i\Theta_{MN}$, such

¹³The $s = 0$ components must satisfy $A_\mu(x) = A'_\mu(ax)$ and $\epsilon(x) = \epsilon'(ax)$ for some auxiliary fields A'_μ and ϵ' . For a given a , if one just defines $A'_\mu(x) := A_\mu(a^{-1}x)$ and $\epsilon'(x) := \epsilon(a^{-1}x)$ then this constraint is simply an identity.

solutions have infinite energy. General fluctuations around such a background in the non-commutative theory would not preserve the $\hat{D}_{\hat{\mu}} = 0$ condition. Imposing this condition is therefore a projection of the non-commutative theory. This projection is consistent with the extended theory we have described in the sense that $\hat{D}_{\hat{\mu}} = 0$ is gauge-invariant under conjugation by a general element $\exp(\epsilon(x, \partial))$. The non-vanishing component of the field strength $[\hat{D}_M, \hat{D}_N]$ for a gauge field with $\hat{A}_{\hat{\nu}} = -ix_{\nu}$ is precisely the field strength $\hat{F}_{\mu\nu}$ (4.5) of the extended theory. The gauge-invariant action obtained in section 4.2 as an integral over position and momentum space is related to the standard non-commutative Yang-Mills action by the projection above.

5.2 Matrix theory realisations

Recall from subsection 4.3.2 that the gauge symmetry realised by the extended theory in Minkowski spacetime is not sufficient to remove all negative norm states from the spectrum (without additional constraints). This issue does not arise in euclidean \mathbb{R}^D where the theory defines a statistical mechanical model of fields transforming in higher spin representations of $SO(D)$. A time direction can be added to this theory to obtain a non-relativistic system in $D+1$ dimensions with spatial $SO(D)$ invariance. One can then consider a sphere S^{D-1} embedded in the euclidean subspace \mathbb{R}^D . This construction is natural in the context of fuzzy spheres which give rise [1],[6] to the class of non-associative algebras we started the paper with. These fuzzy sphere constructions follow as solutions to 0-brane actions (which initially contain a time direction) as used in the BFSS Matrix theory conjecture [42]. The fuzzy spherical worldvolume emerges from matrix degrees of freedom associated with the spatial directions of the spacetime only. The fuzzy \mathbb{R}^D considered above is to be understood as the euclidean embedding space of these fuzzy spheres.

The non-associative lorentzian theory could also arise from a Matrix theory construction where the matrix components are associated with a lorentzian subspace of the physical spacetime. For example, one could attempt to follow the fuzzy sphere construction to obtain a fuzzy de Sitter space from the IKKT Matrix model [43]. In fact, such a formulation could potentially restore full gauge-invariance in the associative limit of the lorentzian theory. The reason is because one classifies positive energy states in dS_D locally¹⁴ via unitary irreducible representations of $SO(D, 1)$ (rather than of $SO(D-1, 1)$ in Minkowski space). This means that one cannot always describe higher spin field theories on flat and curved spacetimes in terms of the same number of degrees of freedom [37]. In particular, for massless theories, gauge symmetry often requires one to introduce compensator fields which are coupled to the fundamental higher spin field in curved space and become decoupled only in the flat space limit.¹⁵ Of course, for massive theories, gauge symmetry

¹⁴Of course, globally, de Sitter space is not causally complete and so this analysis is restricted to a given causal patch.

¹⁵For example, in [37] it was found that the gauge-invariant formulation of a massless “hook” field (in the $(2, 1)$ representation of the local Lorentz group) in anti-de Sitter space requires an additional “graviton-like” compensator field (in the (2) representation of the local Lorentz group). The hook and graviton-like fields are only decoupled in flat space where a fully gauge-invariant description of each massless free field is possible.

implies that the compensator fields must not decouple in flat space [38, 39]. In a similar manner, it is conceivable that the gauge symmetries broken by interaction terms in the extended theory could be restored via compensator fields introduced following a de Sitter space reformulation. It is possible that such a reformulation could have interacting “partially massless” phases, of the kind discovered by Deser and Waldron [36] for free higher spin bosonic theories in de Sitter space, which are unitary despite only realising a reduced gauge symmetry.

5.3 On the non-associative theory

Deviation from the precise Yang-Mills type structure in the non-associative theory on $\mathcal{A}_n^*(T^*\mathbb{R}^D)$ makes the physical properties of the associative theory on $T^*\mathbb{R}^D$ found in section 4 rather difficult to generalise. The appropriate generalisation of the associative equation of motion (4.7) is

$$\hat{D}^\mu \cdot \hat{F}_{\mu\nu} = 0. \quad (5.1)$$

This certainly gauge transforms covariantly (in the non-associative sense defined in section 3) and also reduces to (4.7) in the associative limit. The precise structure of the gauge-invariant action and abelian embedding for the non-associative theory is less clear though.

5.3.1 Non-associative trace

Recall that the construction of a gauge-invariant action for the associative theory relied on the existence of a well-defined symmetric trace. An example of such a map was given in terms of a basis of integrable Wigner functions. We see no obvious obstruction to generalising this to the non-associative case. The explicit construction requires a choice of function that is an appropriate non-associative generalisation of the harmonic oscillator hamiltonian $(-\square + x^2)/2$ used in subsection 4.2.1. The simplest “hamiltonian” function on $\mathcal{A}_n^*(T^*\mathbb{R}^D)$ which reduces to this form in the associative limit is

$$\frac{1}{2}\eta^{\mu\nu}(-\partial_\mu\partial_\nu + x_{\mu\nu}). \quad (5.2)$$

One must then construct a basis of eigenfunctions of this operator on $\mathcal{A}_n^*(\mathbb{R}^D)$. The ground-state of the associative hamiltonian is simply $\psi_0(x) = \exp(-x^2/2)$ (with eigenvalue $D/2$). It is not clear whether the operator (5.2) is also bounded below but a reasonable guess for the corresponding non-associative state would be a “gaussian” of the form

$$\psi_0(x) := \sum_{s=0}^{\infty} \frac{(-1)^s}{2^s s!} x^{\mu_1\mu_2\cdots\mu_{2s-1}\mu_{2s}} \eta_{\mu_1\mu_2} \cdots \eta_{\mu_{2s-1}\mu_{2s}}. \quad (5.3)$$

Of course, this reduces correctly in the associative limit but is not an eigenfunction of (5.2) due to non-associative corrections. In particular, one can show that

$$-\frac{1}{2}\partial_\mu\partial^\mu\psi_0(x) = f(n)\frac{D}{2}\psi_0(x) - g(n)\frac{1}{2}x_\mu^\mu\psi_0(x), \quad (5.4)$$

where the functions $f(n) = 1 - (n-1)/4n^3 + \dots$ and $g(n) = 1 + 1/n + \dots$ are constants on $\mathcal{A}_n^*(\mathbb{R}^D)$ which both equal unity in the associative limit (the dots indicate higher powers in the $1/n$ expansion). The function (5.3) is therefore an exact eigenfunction of the modified hamiltonian $(-\partial_\mu \partial^\mu + g(n)x_\mu^\mu)/2$ with eigenvalue $f(n)D/2$. It is likely that there exist $1/n$ -dependent modifications of the coefficients in (5.3) that make it an exact eigenfunction of (5.2). In this manner we expect the non-associative eigenvalue problem can be solved and the corresponding Wigner functions constructed. Of course, it may be that one has a much larger class of integrable functions than such Wigner functions on the fuzzy space.

5.3.2 Non-associative unfolding

Recall that one of the motivations for the extended theory was the impossibility of a naive formulation of abelian gauge theory on $\mathcal{A}_n^*(\mathbb{R}^D)$. A more sophisticated method might be to consider the embedding (4.37) for the non-associative extended theory. Unfortunately, non-associative operators of this form no longer commute and the constraints (4.37) are not well-defined under gauge transformations. All we can say is that, fundamentally, any consistent embedding must allow all the higher spin components $A_\mu^{\alpha_1 \dots \alpha_s}$ to be solved for in terms of a single component Φ_μ in a gauge-invariant way.

6. Summary and outlook

We analysed gauge theory on a class of fuzzy spaces which correspond to particular non-associative deformations $\mathcal{A}_n^*(\mathbb{R}^D)$ of flat spacetime \mathbb{R}^D . Gauge theory on $\mathcal{A}_n^*(\mathbb{R}^D)$ is most naturally formulated in terms of the non-associative deformation $\mathcal{A}_n^*(T^*\mathbb{R}^D)$ of the cotangent bundle of \mathbb{R}^D . We have extended the discussion in [1] to give explicit formulas for global gauge transformations and field strengths appropriate to describe this non-associative gauge theory. The theory we considered remains non-trivial in the associative limit and can be interpreted as an interacting theory involving an infinite number of higher spin fields on \mathbb{R}^D . We have examined the physical properties of this limit of the theory in some detail.

In principle, the non-associative deformation we defined can be considered for any (pseudo-)Riemannian manifold M . This would proceed by deforming the realisation of such geometries as algebraic curves in flat spaces of suitably large dimension. For euclidean signature spherical spaces, we explained that the non-associative gauge theory can be related to constructions in Matrix theory via fuzzy spheres. The associative limit of the gauge theory on Minkowski space encounters subtleties related to removing all negative norm states from the spectrum by gauge-fixing. We discussed these subtleties and proposed possible solutions. Gauge theory constructions on fuzzy de Sitter geometries from Matrix theory could help resolve such issues.

The extension of fields from functions on M to functions on T^*M also arises in Hull's discussion of W -gravity [44]. This suggests that the related W -geometries may allow non-associative deformations. The physical interpretation of the non-associativity parameter in that context is an interesting question. A cotangent bundle construction for gauge theory on non-associative spaces has also been used in [45], albeit for somewhat different reasons

and for a different class of non-associative algebras. Other descriptions of non-associative gauge theories have been considered in [46]–[48] and [49] though the detailed relation to the formalism we develop here is not yet clear. It may be interesting to explore possible relations between the approach based on loop bundles in [47]–[49] and the approach based on T^*M of this paper. A different type of non-associative generalisation where the gauge group, rather than spacetime, is made non-associative is explored in [50].

The number of higher spin fields required to describe interactions can be related to the non-associativity parameter n of $\mathcal{A}_n^*(\mathbb{R}^D)$. This is because, in the Matrix theory origin of these algebras, n is related to the size of matrices [1]. All our considerations in the present paper (starting from the validity of the derivation property of ∂_μ) have assumed the infinite number of higher spin fields to be independent of the deformation parameter n . However, a more careful treatment of the Matrix theory example could allow the construction of a gauge-invariant interacting theory with finitely many higher spin fields.

A. \hat{E}

In terms of E and F (2.3) (whose explicit form are given in appendix B and [1]), the operator $\hat{E}(\hat{A}, \hat{B})$ (2.6) is given by

$$\begin{aligned} \hat{E}(\hat{A}, \hat{B}) = & \sum_{r,s=0}^{\infty} \frac{1}{r!s!} [E(A^{\mu_1 \cdots \mu_r}, B^{\nu_1 \cdots \nu_s}) * \partial_{\mu_1} \cdots \partial_{\mu_r} \partial_{\nu_1} \cdots \partial_{\nu_s} + \\ & + \sum_{k=1}^s \binom{s}{k} \{B^{\nu_1 \cdots \nu_s} * (\partial_{\nu_1} \cdots \partial_{\nu_k} A^{\mu_1 \cdots \mu_r}) - \\ & \quad - F(B^{\nu_1 \cdots \nu_s}, (\partial_{\nu_1} \cdots \partial_{\nu_k} A^{\mu_1 \cdots \mu_r}))\} * \partial_{\nu_{k+1}} \cdots \partial_{\nu_s} \partial_{\mu_1} \cdots \partial_{\mu_r} - \\ & - \sum_{k=1}^r \binom{r}{k} \{A^{\mu_1 \cdots \mu_r} * (\partial_{\mu_1} \cdots \partial_{\mu_k} B^{\nu_1 \cdots \nu_s}) - \\ & \quad - F(A^{\mu_1 \cdots \mu_r}, (\partial_{\mu_1} \cdots \partial_{\mu_k} B^{\nu_1 \cdots \nu_s}))\} * \partial_{\mu_{k+1}} \cdots \partial_{\mu_r} \partial_{\nu_1} \cdots \partial_{\nu_s}]. \quad (\text{A.1}) \end{aligned}$$

This expression for $\hat{E}(\hat{A}, \hat{B})$ can be arranged in a derivative expansion of the form

$$\hat{E}(\hat{A}, \hat{B}) = \sum_{s=0}^{\infty} \frac{1}{s!} (\hat{E}^{\mu_1 \cdots \mu_s}(\hat{A}, \hat{B}))(x) * \partial_{\mu_1} \cdots \partial_{\mu_s}, \quad (\text{A.2})$$

where the coefficients $\hat{E}^{\mu_1 \cdots \mu_s}(\hat{A}, \hat{B})$ are functions on $\mathcal{A}_n^*(\mathbb{R}^D)$. The $s = 0$ term in this expansion is

$$\hat{E}(\hat{A}, \hat{B}) = \sum_{s=1}^{\infty} \frac{1}{s!} (B^{\mu_1 \cdots \mu_s} * (\partial_{\mu_1} \cdots \partial_{\mu_s} A) - A^{\mu_1 \cdots \mu_s} * (\partial_{\mu_1} \cdots \partial_{\mu_s} B)). \quad (\text{A.3})$$

Unlike in (2.4), this zeroth order term is generally non-vanishing. Notice also that it does not depend on \mathbf{E} nor \mathbf{F} and so does not vanish in the associative limit. The $s = 1$ coefficient function in (A.2) is

$$\begin{aligned} \hat{E}^\mu(\hat{A}, \hat{B}) &= E^\mu(A, B) + \sum_{s=1}^{\infty} \frac{1}{s!} \{F^\mu(A^{\nu_1 \cdots \nu_s}, (\partial_{\nu_1} \cdots \partial_{\nu_s} B)) - F^\mu(B^{\nu_1 \cdots \nu_s}, (\partial_{\nu_1} \cdots \partial_{\nu_s} A))\} + \\ &+ \sum_{s=1}^{\infty} \frac{1}{s!} \{B^{\mu\nu_1 \cdots \nu_s} * (\partial_{\nu_1} \cdots \partial_{\nu_s} A) - A^{\mu\nu_1 \cdots \nu_s} * (\partial_{\nu_1} \cdots \partial_{\nu_s} B)\} + \\ &+ \sum_{s=1}^{\infty} \frac{1}{s!} \{B^{\nu_1 \cdots \nu_s} * (\partial_{\nu_1} \cdots \partial_{\nu_s} A^\mu) - A^{\nu_1 \cdots \nu_s} * (\partial_{\nu_1} \cdots \partial_{\nu_s} B^\mu)\}. \end{aligned} \quad (\text{A.4})$$

The operator $\hat{E}(\hat{A}, \hat{B})$ is still non-trivial in the $n \rightarrow \infty$ limit since it reduces to the commutator $[\hat{B}, \hat{A}]$. The derivative expansion for this commutator can be read off from (A.1) after taking $\mathbf{E}, \mathbf{F} \rightarrow 0$ in the associative limit. In this limit the coefficient functions in (A.2) are given by

$$\begin{aligned} \hat{E}^{\mu_1 \cdots \mu_s}(\hat{A}, \hat{B}) &= \sum_{k=0}^s \binom{s}{k} \sum_{r=1}^{\infty} \frac{1}{r!} \left\{ (\partial_{\nu_1} \cdots \partial_{\nu_r} A^{(\mu_1 \cdots \mu_k)}) B^{\mu_{k+1} \cdots \mu_s) \nu_1 \cdots \nu_r} - \right. \\ &\quad \left. - (\partial_{\nu_1} \cdots \partial_{\nu_r} B^{(\mu_1 \cdots \mu_k)}) A^{\mu_{k+1} \cdots \mu_s) \nu_1 \cdots \nu_r} \right\}, \end{aligned} \quad (\text{A.5})$$

where bracketed indices are to be symmetrised with weight 1.

The coefficients (A.5) generally do not vanish for any s . This statement implies that the commutator algebra of differential operators on \mathbb{R}^D is non-abelian. Notice though that the sum on the right hand side of (A.5) has a symmetry under $k \rightarrow s - k$. Therefore this commutator algebra has an abelian subalgebra generated by operators \hat{H} (of the form (4.1)) whose components satisfy

$$H_{\mu_1 \cdots \mu_s} = \partial_{\mu_1} \cdots \partial_{\mu_s} H, \quad (\text{A.6})$$

for all s (indices have been lowered using the flat metric $\eta_{\mu\nu}$). Indeed (A.5) implies that $[\hat{A}, \hat{B}] = 0$ for any operators \hat{A} and \hat{B} whose coefficient functions both take the form (A.6). The commutator algebra of differential operators on \mathbb{R}^D is infinite-dimensional. Indeed an operator of the form (4.1) has an infinite number of linearly independent component functions. The constraint (A.6) relates all these component fields to the zeroth order scalar function in the expansion of the operator. Consequently the abelian subalgebra defined above is one-dimensional.

B. E and F

As found in [1], the $*$ -product discussed in section 2 can be written in terms of the derivations ∂_μ given in (2.1). Writing the product in this way allows computation of its action on more general functions. For two sets of integers S and T , the $*$ -product rule for basis elements of $\mathcal{A}_n^*(\mathbb{R}^D)$ can be written

$$x^{\mu(S)} * x^{\mu(T)} = \sum_{U \subset S, V \subset T} \frac{1}{n^{2|U|}} \frac{n!}{(n - |U|)!} \partial_{\mu(U \cup V)} x^{\mu(S \cup T \setminus U \cup V)}, \quad (\text{B.1})$$

where $x^{\mu(S)} := x^{\mu_1 \dots \mu_s}$ (the number of elements in S is written $|S| \equiv s$) and $\partial_{\mu(S)} := \partial_{\mu_1} \dots \partial_{\mu_s}$. One can check that the derivations ∂_μ indeed obey the Leibnitz rule when acting on (B.1). The map $m_2^* : \mathcal{A}_n^*(\mathbb{R}^D) \otimes \mathcal{A}_n^*(\mathbb{R}^D) \rightarrow \mathcal{A}_n^*(\mathbb{R}^D)$ is defined such that $m_2^*(x^{\mu(S)} \otimes x^{\mu(T)}) := x^{\mu(S)} * x^{\mu(T)}$. One can also define a *concatenation* product map m_2^c such that $m_2^c(x^{\mu(S)} \otimes x^{\mu(T)}) := x^{\mu(S \cup T)}$. We can write m_2^* in terms of m_2^c using the derivations such that

$$m_2^* = m_2^c \sum_{k=0}^{\infty} \frac{1}{n^{2k}} \binom{n}{k} \partial_{\mu_1} \dots \partial_{\mu_k} \otimes \partial^{\mu_1} \dots \partial^{\mu_k}. \quad (\text{B.2})$$

This equation is of the form

$$m_2^* = m_2^c f(\partial_\mu \otimes \partial^\mu), \quad (\text{B.3})$$

where the function

$$f(x) := \left(1 + \frac{x}{n^2}\right)^n. \quad (\text{B.4})$$

With this expression, f^{-1} is easy to write down and expand. This allows us to recover the inverse formula expressing $m_2^c = m_2^*(f^{-1}(\partial_\mu \otimes \partial^\mu))$, which agrees with (and proves) the formula in appendix 1 of [1]. It should be noted that ∂_μ is also a derivation with respect to a more general product than m_2^* that can be written in terms of m_2^c as above but for *any* function $f(\partial_\mu \otimes \partial^\mu)$. If one considers a function which also depends on the degree operator acting on the polynomials in x^μ then one obtains deformed derivations such as those which follow from the product m_2 in [1]. The remaining formulae are therefore also valid for more general products expressed as in (B.3) but for any f that is a function of $\partial_\mu \otimes \partial^\mu$ only.

Using the fact that the concatenation product is associative now enables us to give expressions for the associativity operators E and F (2.3) in terms of the function f . Let us begin by defining a map Δ from the space of multiple derivatives of $\mathcal{A}_n^*(\mathbb{R}^D)$ to the tensor product of two copies of this space. That is

$$\Delta(\partial_{\mu(S)}) := \sum_{U \cup V = S} \partial_{\mu(U)} \otimes \partial_{\mu(V)}. \quad (\text{B.5})$$

Consequently, we can write $\partial_{\mu(S)} m_2^* = m_2^* \Delta(\partial_{\mu(S)})$ when acting on $\mathcal{A}_n^*(\mathbb{R}^D) \otimes \mathcal{A}_n^*(\mathbb{R}^D)$. The same equation also holds when we replace m_2^* with m_2^c , since ∂_μ also obeys the Leibnitz rule with respect to m_2^c .

Now consider the product $A * (B * C)$ for any three functions on $\mathcal{A}_n^*(\mathbb{R}^D)$,

$$\begin{aligned} A * (B * C) &= m_2^*(1 \otimes m_2^*)(A \otimes B \otimes C) \\ &= m_2^c f(\partial_\mu \otimes \partial^\mu)(1 \otimes m_2^c) f(1 \otimes \partial_\nu \otimes \partial^\nu)(A \otimes B \otimes C) \\ &= m_2^c(1 \otimes m_2^c)((1 \otimes \Delta) f(\partial_\mu \otimes \partial^\mu)) f(1 \otimes \partial_\nu \otimes \partial^\nu)(A \otimes B \otimes C), \end{aligned} \quad (\text{B.6})$$

which can be rearranged using associativity of m_2^c to give

$$\begin{aligned} &= m_2^* f^{-1}(\partial_\mu \otimes \partial^\mu)(m_2^* \otimes 1) f^{-1}(\partial_\nu \otimes \partial^\nu)((1 \otimes \Delta) f(\partial_\rho \otimes \partial^\rho)) f(1 \otimes \partial_\sigma \otimes \partial^\sigma)(A \otimes B \otimes C) \\ &= m_2^*(m_2^* \otimes 1)((\Delta \otimes 1) f^{-1}(\partial_\mu \otimes \partial^\mu)) f^{-1}(\partial_\nu \otimes \partial^\nu)((1 \otimes \Delta) f(\partial_\rho \otimes \partial^\rho)) \times \\ &\quad \times f(1 \otimes \partial_\sigma \otimes \partial^\sigma)(A \otimes B \otimes C). \end{aligned} \quad (\text{B.7})$$

This manipulation has expressed the product $A * (B * C)$ in terms of a sum of products involving derivatives of the functions A , B and C (where the $*$ -multiplication of the first two entries is done first and so is similar in structure to $(A * B) * C$). Thus the F operator in (2.3) can be read off from

$$\begin{aligned} F(A, B)C &= m_2^*(m_2^* \otimes 1)[1 - ((\Delta \otimes 1) f^{-1}(\partial_\mu \otimes \partial^\mu)) f^{-1}(\partial_\nu \otimes \partial^\nu) \times \\ &\quad \times ((1 \otimes \Delta) f(\partial_\rho \otimes \partial^\rho)) f(1 \otimes \partial_\sigma \otimes \partial^\sigma)](A \otimes B \otimes C), \end{aligned} \quad (\text{B.8})$$

in terms of derivatives acting on C (as in (2.4)). The analogous derivative expansion of the E operator immediately follows, since $E(A, B) = F(A, B) - F(B, A)$.
