February, 1955

ABSTRACT

The data presented in this report are the results of two instrumentations, each consisting of a single modified Bendix J-8 Attitude Gyroscope mounted in two trial positions. The application of the instrument to use in a missile requires an extensive modification and testing program, viz., the conventional "erector-mechanism" is removed, a suitable mass replaces it, and the entire instrument is balanced in such a way that the center of gravity coincides with the intersection of the two rotation axes. This erector mechanism, in the conventional use of the gyro in aircraft, maintains the axis of the gyrostat normal to the earth's surface.

Of the two instrumentations, one considered by this agency as the conventional unit, is called "Beta-gyro" to connote the position and the scale markings. The other mounting position, called the "Psi-gyro" was an experimental one and was thought to be less favorable to the instrument but more favorable to the data analysis. In the design of the aspect experiment, the Beta-gyro was the primary measure serving to evaluate the performance of the Psi-gyro. Missile evaluation was considered necessary, since the results of simulation tests for gravity effects in the laboratory were inconclusive.

EXPERIMENTAL OBJECTIVE

Aerobee AF-48, fired 14 July 1955, was used in this experiment in an attempt to evaluate the long-term stability of gyroscopes as related to their use as missile-aspect monitors. The data output from two gyroscopes carried by this missile are given in this report for the ultimate purpose of comparison with a conventional photographic aspect system.

REFERENCE FRAMES

The data contained in this report are given as the classical Eulerian Angles with the initial positions chosen by New Mexico A and M College in their aspect experiments. The coordinates are defined in their report as follows:

"Figure 1 demonstrates two right-handed...orthogonal coordinate systems. The reference coordinate system, $X^0Y^0Z^0$, has the origin at the base of the missile; the X^0Y^0 plane is parallel to a plane tangent to the earth at the sub-missile point. X^0 is positive west, Y^0 positive north, and Z^0 vertical.

The missile coordinate system, XYZ, has a common origin to $X^0Y^0Z^0$. Z represents the missile longitudinal axis, X an axis passing through the periphery of the missile in an eastward direction, Y northward. Initially the two systems will be coincident. Any unique orientation of the missile can be described by the three successive counterclockwise angles of rotation (Θ , Φ , Ψ) about specified axes.

Figure 1 represents a missile rotation about the Z axis, displacing X from X^0 by an angle Φ . Figure 2 demonstrates a rotation about the Y axis displacing Z from Z^0 by an angle Θ , the zenith angle. It is seen that X is also displaced from the X^0Y^0 . Φ is thus seen to be the 'heading' or azimuth angle, measured counterclockwise from east. Figure 3 shows a rotation about the Z axis displacing Y from K, the line of intersection of the two planes through Ψ , the 'swivel roll' angle. Thus the three Eulerian angles are demonstrated."

The times given in the report are derived from a calibrated "Counter Clock". This consists of a numerical display system driven by a d-c, governed motor, photographed simultaneously with the gyroscopes. In addition, two timing pulses generated by the telemetry commintator were displayed by two glow lamps in the photo field. These timing pulses, called "half-second-light" and "twelve-second'light", are not to be construed as accurate time bases, but rather as reference marks occurring at a somewhat uniform rate and intended for use in correlating concurrent experiments in the missile. The period between pulses approximates one and one-half seconds and fourteen seconds, respectively. The pulse's presence is indicated by an "x" in the tabular data.

ENGINEERING RESEARCH INSTITUTE • UNIVERSITY OF MICHIGAN

Time is not given for every set of data in the table; however, the counter-clock values are and can be converted into time-after-take-off through the relationship

$$\text{time(sec)} = \frac{\text{Counter Clock number} - 78895}{10.89}$$

EXPERIMENTAL RESULTS

Unfortunately, through an oversight at the last instrument check prior to fueling, a rubber gasket fell against the Beta-gyrostat in a manner suggesting intermittent contact. The recording camera observed such proximity with the gyrostat until the time of burn-out (34 seconds), when the interfering gasket left the camera field, allowing the gyro to perform freely. With such a constraint the Beta-gyro could precess; however, an examination of the record in terms of the ψ -gyro indicates the precession to be small due to the constraint. A qualifying remark in regards to ψ -gyro data validity is necessary, since the examination of the recovery instrumentation indicated that the fuse in the ψ -gyro power supply opened during the sampling time or at impact. Physical evidence in addition to the instrument's behavior after x-plus-three-minutes suggests that the fuse failed at take-off, leaving the ψ -gyro without power during the flight. Laboratory observations indicate that such a gyro should perform satisfactorily for approximately 140 seconds in a missile. The total precession at that time should not exceed 3° in any given angle. At times greater than 140 seconds the gyrostat will have lost so much of its angular momentum as to make the instrument unreliable after 180 seconds. Under these circumstances, where both gyroscopes are suspect, no calculation could be made for the upper bound of the θ -angle error or the ψ -angle error for values presented in this tabulation. It will be evident that the ϕ angle is left undefined; this follows, since its value depends on the θ - and ψ -angles in a manner requiring precision in these angles for good values of ϕ . It was decided to leave the ϕ -angle undefined rather than give meaningless values.

CONCLUSIONS

Results derived from this experiment must be considered inconclusive in the light of the malfunctions encountered; however, the data agreement between the ψ -gyro and β -gyro is more than reasonable after making corrections for aberrations of the respective instruments. The agreement is enough to suggest another experiment having only the ψ -gyro for comparison with the photographic aspect system. The long-time stability of the gyroscopes is still undetermined and, as such, should be a major topic in any subsequent experiment. Such an experiment should involve a maximum altitude of over 60 miles and be compared with an aspect system for times of approximately x plus 240 seconds. Use of the ψ -gyro is desirable in aspect applications because of the extensive reduction in data analysis and subsequent relaxation of mechanical specifications imposed in building and testing such gyroscopes.
