### **Monitoring the Future: A Continuing Study of the Lifestyle and Values of Youth**

As its title suggests, this study is intended to assess the changing lifestyles, values, and preferences of American youth on a continuing basis. Each year since 1975, about 17,000 seniors have participated in the annual survey, which is conducted in some 130 high schools nationwide. Since 1991, the study's annual surveys also have included surveys of similar nationally representative samples of eighth and tenth grade students. In addition, subsamples of seniors from previously participating classes receive follow-up questionnaires by mail each year.

This Occasional Paper Series is intended to disseminate a variety of products from the study, including pre-publication (and somewhat more detailed) versions of journal articles, other substantive articles, and methodological papers.

A full listing of occasional papers and other study reports is available on the study's Web site, [www.monitoringthefuture.org](http://www.monitoringthefuture.org). The Web site contains a complete listing of all publications from the study, the abstracts or full text of many of these publications, and recent press releases.

The mailing address of Monitoring the Future is Institute for Social Research, The University of Michigan, P.O. Box 1248, Ann Arbor, MI 48106.

## INTRODUCTION

The Monitoring the Future (MTF) project reports annually on levels and trends in self-reported substance use by secondary school students (e.g., Johnston, O’Malley, Bachman, & Schulenberg, 2009). The reports include subgroup comparisons, and these have revealed substantial differences among race/ethnicity groups, as well as some differences linked to parental education (as the available indicator of socioeconomic level). These comparisons are complicated by the substantial differences in racial/ethnic composition across levels of parental education. The present paper disentangles the confounding of race/ethnicity with parental education by examining the three largest race/ethnicity groups separately, showing and comparing how parental education is related to three common forms of substance use/abuse among adolescents. We show important interaction effects: The negative relationship between parental education and substance use is more pronounced among White adolescents than among those who are African American or Hispanic. We also unmask relationships between parental education and substance use that are clearer for White adolescents than for the total sample.

### **Background**

In addition to the annual reports cited above, there have been a number of articles over the years presenting MTF findings on racial/ethnic subgroups. The first of these was Bachman et al. (1991), reporting differences in smoking, drinking, and illicit drug use among high school seniors in the classes of 1976–1989; a later report by Wallace et al. (2002) extended the coverage to the senior classes of 1976–2000; another report (Wallace et al., 2003) extended coverage to include 8th and 10th graders as well as seniors. Wallace and Muroff (2002) examined a wide range of risk factors for substance use, and found that among 12th graders African Americans were more likely than whites to experience economic deprivation, but economic disadvantage was a stronger predictor of substance use among whites. Wallace and Bachman (1991) also examined background factors, including parental education, as potential explanations of racial/ethnic differences in adolescent drug use; they concluded that controlling for background alone did not account for most such differences. A recent report by Wallace et al. (2009) examined a number of indicators of socioeconomic status (SES) as they related to smoking among 8th-grade girls, and found that parental education was a particularly strong predictor of smoking. The present paper focuses on a single indicator of SES (parental education), and extends coverage to include both genders, all three grades covered by MTF in-school surveys (8th, 10th, and 12th), and the three most frequently used substances (cigarettes, alcohol, and marijuana). Most important, as urged by Wallace and Muroff (2002), the present analyses are “race-specific,” examining patterns separately for race/ethnic subgroups of African-American, Hispanic, and White adolescents.

## METHODS

### **Samples**

In order to provide sufficiently large numbers of cases for the subgroups shown here, we combine findings across the 10 most recent available MTF surveys of 8th-, 10th-, and 12th-grade students—1999–2008. Although prevalence rates for substance use have

changed during that decade, the patterns of relationship reported here have not shifted markedly. The appendix to this occasional paper compares product-moment correlations and linear regression results for five-year intervals (1999–2003 vs. 2004–2008), and shows that very few regression coefficients differ significantly. Specifically, for total samples of males and females, 4 out of 30 comparisons show differences significant at the .05 level (2-tailed), and in each of these the product-moment correlations differ by only 0.02; for comparisons showing the three racial/ethnic subgroups separately, only 7 out of 90 comparisons are significant, and none is large or important.

MTF sampling and data collection methods are described in detail elsewhere (Bachman, Johnston, O’Malley, & Schulenberg, 2006; Johnston et al., 2009). Briefly, the study uses a multistage sampling procedure to obtain nationally representative samples of 8th, 10th, and 12th graders from the 48 contiguous states. Stage 1 is the selection of geographic region; Stage 2 is the selection of specific schools—approximately 420 each year; and Stage 3 is the selection of students within each school. This sampling strategy has been used to collect data annually from high school seniors since 1975 and from 8th and 10th graders since 1991. Sample weights are assigned to each student to take into account differential probabilities of selection. Students complete self-administered, machine-readable questionnaires during a normal class period. Student response rates average about 90% for 8th graders, 86% for 10th graders, and 84% for 12th graders. Absence on the day of data collection is the primary reason that students are missed; it is estimated that less than one percent of students refuse to complete a questionnaire.

### **Measures of Race/Ethnicity and Parental Education**

These measures are described in greater detail in Johnston et al. (2009, pp. 497–498):

*Race/Ethnicity.* In the early MTF surveys, respondents were presented with a list of various racial/ethnic categories. General instructions told the respondents to mark only one answer. In 2005 a random half of the respondents were presented with the list of racial/ethnic categories and instructed to “select one or more responses”; relatively few respondents (about 6%) selected more than one category. In 2006 and thereafter the revised instruction was used in all forms. For the original question, respondents were assigned to the racial/ethnic group specified in their response. For the revised question, those checking only White and no other racial/ethnic group were categorized as White; those checking Black or African American and no other racial ethnic group were categorized as African American; and those checking Mexican American or Chicano, Cuban American, Puerto Rican, or other Hispanic or Latino and no other racial/ethnic group were categorized as Hispanic Those checking multiple racial/ethnic groups or one of the other specified groups are omitted from the reporting on race/ethnicity in this article, because of the small numbers of cases.

- White: Consists of those respondents who describe themselves as White or Caucasian in 1975–2004. In 2005 the unchanged questionnaire forms were treated in a similar manner and the changed forms were treated in the manner described above. Beginning in 2006 all forms were treated in the manner described above.

- African American: Consists of those respondents who in 1975–1990 describe themselves as Black or Afro-American or who, in 1991–2004, describe themselves as Black or African American. In 2005 the unchanged questionnaire forms were treated in a similar manner and the changed forms were treated in the manner described above. Beginning in 2006 all forms were treated in the manner described above.
- Hispanic: Consists of those respondents who in 1975–1990 describe themselves as Mexican American or Chicano, or Puerto Rican or other Latin American. After 1990 this group includes those respondents who describe themselves as Mexican American or Chicano, Cuban American, Puerto Rican American, or other Latin American. After 1994, the term “Puerto Rican American” was shortened to “Puerto Rican.” In 2005 the unchanged questionnaire forms were treated in a similar manner and the changed forms were treated in the manner described above. Beginning in 2006 all forms were treated in the manner described above.

*Parental Education.* This is an average of mother’s education and father’s education based on the respondent’s answers about the highest level of education achieved by each parent, using the following scale: (1) completed grade school or less, (2) some high school, (3) completed high school, (4) some college, (5) completed college, (6) graduate or professional school after college. Missing data was allowed on one of the two variables. The respondent is instructed, “If you were raised mostly by foster parents, stepparents, or others, answer for them. For example, if you have both a stepfather and a natural father, answer for the one that was most important in raising you.”

### **Measures of Substance Use**

Five dichotomous measures are shown in the figures reporting substance use prevalence. These include any use of cigarettes during the past 30 days, consumption of five or more alcoholic drinks in a row on at least one occasion during the past two weeks, and any use of marijuana during the past 12 months. These three measures are identical across all surveys and are described in detail in other publications (Bachman et al., 2006; Johnston et al., 2009). Analyses of MTF panel data have found that patterns of cross-time correlations for these substance use measures, including estimates of reliability, have been largely consistent over several decades (Bachman, Wadsworth, O’Malley, Johnston, & Schulenberg, 1997; Bachman et al., 2002). The fourth measure is any inhalant use during the past 12 months; the question asks, “On how many occasions (if any) have you snuffed glue, or breathed the contents of aerosol spray cans, or inhaled any other gases or sprays in order to get high?” The fifth measure is any use during the past 12 months of an illicit drug other than marijuana; the drugs include LSD, other hallucinogens, crack, other cocaine, heroin, any narcotics other than heroin, amphetamines, sedatives (barbiturates), or tranquilizers not used under a doctor’s orders (however, for the 8th and 10th graders, the use of sedatives and the use of narcotics other than heroin have been excluded from this measure because younger respondents appear to overreport such use—perhaps because they sometimes include the use of nonprescription drugs in their answers).

### **Analysis Approach**

Our reporting here is descriptive. For each type of substance use we provide figures showing prevalence rates (percentages reporting use) at each level of parental education, with patterns shown separately for total samples of males and females, and for three subgroups of male adolescents (White, African American, and Hispanic) and the corresponding three subgroups of female adolescents. The figures also include unstandardized linear regression coefficients, with any that fall short of significance at the .05 level (2-tailed) indicated as *ns*. (As noted above, the unstandardized regression coefficients, as well as product-moment correlations, are presented also in the appendix; included there are complete *p*-values—i.e., 2-tailed probabilities that the relationship occurred by chance.) The calculations were done with the SURVEYREG procedure in SAS version 9, and *p*-values incorporated appropriate adjustments for clustered sample designs.

## **RESULTS**

The distributions of (weighted) cases by race/ethnicity and parental education are shown in Table 1 (males and females combined). The table clearly indicates that the parents of Hispanic adolescents have much lower than average educational levels. The row percentages in Table 1 show that 29–33% of Hispanic respondents had parents in the lowest education category, contrasted with only 8–9% of African-American respondents and less than 5% of White respondents. Turning to the column percentages in Table 1, we can see that nearly half (42–46%) of all adolescents with parents in the bottom category of parental education are Hispanic, about one third (32%) are White, and 12–13% are African American, with the remaining 10–13% spread across all other race/ethnicity subgroups. The column percentages also show that Whites comprise fully two thirds of the 8th graders and nearly three quarters of 10th and 12th graders with parents in the top two categories of educational attainment.

The next sections show how this heavy proportion of Hispanic students and relatively low proportion of White students in the bottom category of parental education can produce somewhat misleading patterns of drug use findings when students from all race/ethnicity subgroups are combined. We look first at cigarette use, then at instances of heavy drinking, and finally at use of illicit drugs. For each class of substance use in turn, we first examine links with parental education for all students combined; then we look at those same linkages separately for White, African-American, and Hispanic students.

### **Cigarette Use**

Figure 1 presents prevalence of cigarette use (percent reporting any use in the last 30 days) for 8th-, 10th-, and 12th-grade students, as a function of parental education levels; Part A shows males, and Part B shows females (a convention used for all figures). Among 8th graders, the figure shows a fairly strong negative linear relationship, with smoking declining by an estimated 2.8 percentage points among males and 3.6 points among females for each increment in parental education level. Among 10th graders the relationship is similar but weaker, with no appreciable difference between the bottom two categories of parental education. Among 12th graders, the pattern clearly departs from

linearity, with those in the lowest category of parental education showing lower percentages of smokers than those in the next lowest categories.

Figure 2 shows cigarette use as a function of parental education, but this time for the three racial/ethnic subgroups separately, and we can see pronounced disparities. Among White students there are strong and largely linear negative relations, which are most marked among females and younger students. Among African-American students, smoking prevalence is a great deal lower overall; it shows only small negative relations with parental education among males, and even smaller negative relations among females (and only in 8th and 10th grades). Among Hispanic students, smoking prevalence rates among those with the least educated parents are generally quite low, and not appreciably different from the rates for African-American students. At the higher levels of parental education, the prevalence rates for Hispanic students are somewhat higher than those for African-American students.

In sum, Figure 2 shows that it is only among White students that clear negative relations appear between parental education levels and smoking. Among African Americans, such a pattern is far weaker and not entirely consistent, and among Hispanic students the pattern is mostly irregular across grades and genders. But because the proportions of students with low educated parents is much higher in the minority subgroups, especially the Hispanic students, the regression coefficients for the total samples, shown in Figure 1, are distinctly weaker than those for White students shown in Figure 2.

### **Heavy Drinking**

Figure 3 shows that for the total samples, instances of heavy drinking (five or more drinks in a row at least once in the past two weeks) are less likely among 8th-grade students with highly educated parents. Indeed, when students with the highest levels of parental education are compared with those having the least educated parents, heavy drinking is only half as likely among females and about one third as likely among males. By 10th grade this overall relationship is greatly weakened, and by 12th grade it is actually slightly reversed, with instances of heavy drinking a bit less likely among those with the least educated parents.

When we look at the three race/ethnicity subgroups separately, in Figure 4, we see again a degree of unmasking—albeit not as pronounced as we saw for cigarette use. In 8th grade, instances of heavy drinking show a clear and largely linear negative relation with parental education among White students, but very little relation among the minority subgroups. By 10th grade the negative relation among White students is weaker, and by 12th grade it has disappeared. Among African-American and Hispanic students, the patterns are perhaps best described as irregular, with little consistency across grades or genders—except, of course, for the often noted finding that instances of heavy drinking are substantially less frequent among African-American students compared with the other groups.

Why do instances of heavy drinking increase between 10th and 12th grade among White students with well-educated parents? Other MTF analyses have shown a kind of

“catching up” in alcohol use among college-bound students (i.e., those with good grades and definite plans to obtain a college degree, who on average also have better educated parents); this has been attributed to their greater likelihood of spending time with older friends and siblings already in college, thus exposing them to the heavy drinking college scene (Bachman et al., 2008; Johnston et al., 2009), as well as anticipatory socialization (Schulenberg & Maggs, 2002). Figure 4 illustrates this pattern among White students; there is also some suggestion of a similar pattern among Hispanic students, but not among African-American students.

### **Marijuana Use**

We examined findings for annual marijuana use (any use in the 12 months preceding the survey) as well as findings for use of *any* illicit drug (*including* marijuana). The results are closely overlapping, because the use of marijuana dominates the any illicit drug use measure; accordingly, we focus here on the findings specific to marijuana use.

Figure 5 shows that, for the total samples of male and female 8th graders, annual marijuana use is two to three times as likely among those with the least educated parents, compared with those with the most educated parents. By 10th grade the relationship is still negative, but a bit weaker; by 12th grade the pattern is essentially flat (regression coefficients slightly positive, but nonsignificant).

Figure 6 shows unmasking that bears some similarities to that shown in earlier figures. The negative links between parental education and marijuana use are strongest among White adolescents, although by 12th grade the pattern is flat among males and greatly reduced among females. African-American 8th and 10th graders also show negative relations, but to a lesser extent. The patterns for Hispanic students are moderately (but significantly) negative among 8th graders, whereas among 10th and 12th graders those with the least educated parents show relatively low marijuana use.

### **Use of Illicit Drugs other than Marijuana**

MTF annual reports include a measure of any illicit drug use other than marijuana. We examined that measure (any such use in the past 12 months), and the results are shown in Figures 7 and 8. In general, the findings are similar to, but weaker than, those for marijuana. Among Whites there are modest negative links with parental education, which become weaker (but remain statistically significant) by 12th grade; among Hispanics and African Americans the relationships are generally very small and nonsignificant. Much the same can be said for the measure of inhalant use (in the past 12 months), the results for which are shown in Figures 9 and 10.

## **DISCUSSION**

The results clearly indicate the following: (a) High proportions of Hispanic students have parents at the bottom category of education, and their levels of substance use average distinctly lower than those of White students at that same bottom category of parental education. This contributes heavily to the departures from linearity in the total sample data linking parental education and substance use. (b) The patterns for the three

subgroups show distinct differences—among African-American and Hispanic students, overall levels of substance use are lower and are also linked less strongly and clearly with parental education levels (i.e., interaction effects). (c) The strong negative relations shown by White 8th and 10th graders are diminished among White 12th graders, especially with respect to instances of heavy drinking and marijuana use.

When Wallace and Bachman (1991) explored possible explanations of racial/ethnic differences in drug use among 12<sup>th</sup> graders, they employed a broad additive model which presumed that “...background...variables impact the drug use of young people from different racial/ethnic subgroups in much the same way” (p. 348). The present findings clearly indicate that such a presumption is not valid. Low parental education appears to be a risk factor for White students, especially in 8th and 10th grades, whereas substance use among African-American and Hispanic students is not strongly linked with parental education. So one implication of the present research is that background factors such as parental education may predict substance use among White students, and thus may retain predictive value for total samples consisting largely of Whites; nevertheless, it is not correct to assume that the same sorts of relations hold within other racial/ethnic subgroups.

Finally, it must be kept in mind that the findings reported here are based on *students*, not total age groups. There are differences among the three subgroups in school retention, especially at the upper grade levels. Moreover, school retention rates are poorer among students with less educated parents.
