**Running title:** CNF1 Promotes Prostate Cancer Progression.

The authors declare no conflict of interest.
ABSTRACT

Uropathogenic *Escherichia coli* (UPEC) is the leading cause of urinary tract infections and plays a role in prostatic carcinogenesis and prostate cancer (PCa) progression. However, the mechanisms through which UPEC promotes PCa development and progression are unclear. Cytotoxic necrotizing factor 1 (CNF1) is one of the most important UPEC toxins and its role in PCa progression has never been studied. We found that UPEC-secreted CNF1 promoted the migration and invasion of PCa cells and PCa metastasis. *In vitro* studies showed that CNF1 promotes pro-migratory and pro-invasive activity through entering PCa cells and activating Cdc42, which subsequently induced PAK1 phosphorylation and upregulation of MMP-9 expression. CNF1 also promoted pulmonary metastasis in a xenograft mouse model through these mechanisms. PAK1 phosphorylation correlated with advanced grades of PCa in human clinical PCa tissues. These results suggest that CNF1 derived from UPEC plays an important role in PCa progression through activating a Cdc42-PAK1 signal axis and upregulating the expression of MMP-9. Therefore, surveillance for and treatment of *cnf1*-carrying UPEC strains may diminish PCa progression and thus have an important clinical therapeutic impact.

KEYWORDS

Cytotoxic Necrotizing Factor 1; Uropathogenic *Escherichia coli*; Prostate Cancer;
Cdc42; PAK1.
Introduction

Uropathogenic *Escherichia coli* (UPEC) is the leading cause of urinary tract infections (UTIs), accounting for most community (~95%) and hospital acquired (~50%) infections [1]. UTIs caused by UPEC can induce cystitis, pyelonephritis and prostatitis [2,3]. In addition to being frequently isolated from urine samples of patients with cystitis and pyelonephritis, UPEC is also detected in urine, prostatic secretions and seminal fluids of patients with prostate cancer (PCa), benign prostatic hyperplasia (BPH) and prostatitis [4,5].

PCa is one of the most common cancers in the western world [6]. In the United States, approximately 2.8 million men are diagnosed with PCa each year, which represents 4 in 10 male cancer survivors and 1 in 5 of all cancer survivors [7]. In 2016, it is estimated that there will be 180,890 new PCa cases and 26,120 PCa-related deaths in the United States, resulting in PCa as being the most common form of cancer (21%) and ranking as the second most frequent cause of cancer-related death (8%) [8]. Although PCa is not the most common cancer in China, its incidence and mortality rates are rapidly increasing [9]. The five-year relative survival rate for localized PCa is very high; however, it is low for men with advanced PCa [8].

UPEC infection of male C3H/HeOuJ mice results in prostatic intraepithelial neoplasia (PIN) at 12 weeks, and high-grade prostate dysplasia and invasive PCa 26 weeks after infection [10]. UPEC can accelerate prostatic carcinogenesis induced by 2-amino-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP), a dietary carcinogen, and reduces the survival of rats [11]. Pro-oncogenic epithelial changes were found in the
prostates of C57BL/6J mice 8 weeks post-infection with UPEC [12]. In the genetically engineered Hi-Myc murine PCa model, significantly more UPEC-infected mice had invasive cancer compared to saline-treated mice [12].

Cytotoxic necrotizing factor 1 (CNF1) is a key UPEC toxin. After binding to the surface of epithelial cells, CNF1 is internalized by endocytosis and subsequently transferred to an endosomal compartment, resulting in the enzymatic domain of CNF1 being translocated into the cytoplasm [13,14]. CNF1 induces deamidation of specific glutamine residues of several Rho GTPases including RhoA, Rac1 and Cdc42, resulting in their activation and cell motility [15-18]. The cnf1 gene can be detected in UPEC strains isolated from patients with prostatitis and in tissue samples of BPH [3,19,20]. The prevalence of cnf1 in UPEC strains from prostatitis samples is higher than that of samples from cystitis and pyelonephritis [5]. It has also been reported that the prevalence of E. coli strains harboring cnf1 is higher in biopsies of patients with colorectal cancer than patients with diverticulosis, which implies a role of CNF1 in cancer [21].

In this study, we investigated the role of CNF1 in the motility and invasiveness of PCa cells and PCa metastasis and explored the signaling mechanisms through which CNF1 achieved its activity in PCa progression.
Materials and Methods

Cell lines and reagents
The sources of cell lines and reagents are as follows: PC3, LNCaP, 22Rv1 and VCaP (ATCC, Manassas, VA), the Cdc42 inhibitor CID44216842, RhoA inhibitor CCG-1423, and PAK1 inhibitor IPA3 (SML0918, SML0987 and I2285, Sigma-Aldrich, St. Louis, MO), the Rac1 inhibitor EHT 1864 (HY-16659, MedChem Express, New Jersey, USA).

Bacterial strains and plasmids
The bacterial strains and plasmids used in this study are listed in Table S1. All strains were grown at 37°C in Luria-Bertani (LB) medium for 12 h. When antibiotics were required, they were used at the following final concentrations: kanamycin at 50 μg/ml, ampicillin at 100 μg/ml. The cnf1 gene from UPEC strain 1 and 11 were amplified by PCR and cloned into pET-28a(+) or pTRC99A. The cDNAs coding for Cdc42 or PAK1 were subcloned into pCMV-Myc or pEGFP-N1. The constructed plasmids and primer sequences are listed in Tables S1 and S2.

CNF1 recombinant protein expression and purification
CNF1 was purified as previously described [16]. The purified protein was also
identified by LC-MS/MS: The corresponding band was excised and subjected to in-gel digestion. Resulting peptides were separated by reverse phase liquid chromatography on an easy-nLC 1000 system (ThermoFisher Scientific, Waltham, MA, USA) and directly sprayed into a Q-Exactive mass spectrometer (ThermoFisher). All MS/MS spectra were searched against the Uniprot-ecoli protein sequence database using the PD search engine (version 2.1.0, ThermoFisher) with an overall false discovery rate (FDR) for peptides of less than 1%.

**Mutagenesis**

Mutagenesis of *cnf1*, *CDC42* and *PAK1* were performed by a round circle polymerase chain reaction-based site-directed Fast Mutagenesis System kit (TransGen Biotech, Beijing, China) according to the manufacturer’s protocol. The primers used for mutation were WQ0434 to WQ0437, WQ0465-2 to WQ0468 and WQ0561 to WQ0568 (Table S2).

**Wound healing assay**

PC3 were grown to 95%-100% confluency and wounds generated with a 200 μL pipette tip, and treated with buffer, LPS or CNF1 (1 nMol/L). Images of wound healing were taken at the indicated time intervals using a microscope (Leica Microsystems, Wetzlar, Germany). The wound area was measured by Image J software.

**Transwell migration and invasion assay**

Cell migration and invasion assays were performed using Transwell chambers (pore size of 8 μm, Costar, Corning 3422), with Corning Matrigel Matrix (Corning...
Incorporated, Corning, NY, USA) for invasion assays. The inserts were placed in 24-well culture plates. Cells were resuspended in serum-free RPMI 1640 medium. PC-3 cells (2 × 10^5 in 200 μl) were added to the upper chamber of uncoated (for migration assays) or Matrigel coated (for invasion assays) membranes with CNF1 (1 nMol/L), LPS, or buffer. 600 μL of medium containing 20% fetal bovine serum with CNF1 (1 nMol/L), LPS or buffer was added to the lower chamber as chemoattractant. After 12 h (migration assays) or 24 h (invasion assays) incubation at 37°C in a 5% CO₂ humidified atmosphere, the cells that had not migrated through the pores were manually removed from the upper face of the filters using cotton swabs, and cells adherent to the bottom surface of the inserts were fixed in 4% paraformaldehyde for 1 h and stained with 0.1% crystal violet (Beijing Solarbio Science & Technology Co., Ltd., Beijing, China) for 15 min. Finally the filters were washed three times in PBS and images taken under a microscope (Leica Microsystems) with 200 × magnification.

**Immunofluorescence analysis**

Cells were grown on glass coverslips, fixed with 4% paraformaldehyde for 15 min and blocked with phosphate-buffered saline (PBS) containing 10% goat serum for 60 min. Cells were incubated with CNF1 antibody (Santa Cruz Biotechnology, Santa Cruz CA, USA, sc-52655, 1:200) in PBS at 4°C overnight, washed three times with PBS, incubated with Alexa Fluor 488-labeled secondary antibody (Life Technologies, Gaithsburg MD, USA) in PBS for 1 h and analyzed using a confocal fluorescence microscope (FV1000-D, Olympus, Tokyo, Japan).
**Rho GTPase activation assays**

PC3 cells were seeded in 10 cm dishes. After treatment, Cdc42-, Rac1- and RhoA-activation were measured using the respective Activation Assay Biochem Kit (Cdc42: BK034; Rac1: BK035; RhoA: BK036, Cytoskeleton, Dencer CO, USA) according to the manufacturer’s protocol.

**Antibodies and western blotting**

Antibodies were obtained from the following companies: anti-Phospho-PAK1 (Thr423) (#2601, 1:1000), anti-PAK1 (#2602, 1:1000) from Cell Signaling Technology, Danvers MA, USA; anti-MMP2 (sc-10736, 1:500), anti-CNF1(sc-52655, 1:500) from Santa Cruz; anti-MMP9 (PB0709, 1:500) from BOSTER WuHan, China). Cells were washed by PBS three times after treatment with CNF1 or dialysis buffer. Whole cell lysates were prepared using RIPA lysis buffer (Millipore Billerica, MA, USA), adding complete protease inhibitors and phosphatase inhibitors (Roche, Basel, Switzerland). Protein concentration was determined using the BCA Protein Assay Kit (ThermoFisher) and approximately 40 µg of cell lysates were used. Antibody binding was revealed using an HRP-conjugated anti-rabbit IgG or anti-mouse IgG (Sigma-Aldrich). Antibody complexes were detected using Immobilon Western Chemiluminescent HRP Substrate (Millipore) and exposure to Tanon-5200 machine. Densitometry was performed using Image J software.

**Transduction and transfection**

PC3 or 22Rv1 cells stably expressing luciferase were constructed using lentiviral supernatant and selected with puromycin following the manufacturer’s instructions.
PC3-luci cells stably expressing CNF1 or CNF1-C866S (AA 515-1014) were constructed using lentiviral supernatant. PC3 and 22Rv1 cells were transiently transfected with the Cdc42 and PAK1 related plasmids using Lipofectamine 2000 (Invitrogen, Carlsbad, CA).

**Tumor xenograft model**

Male NOD/SCID mice were purchased from Academy of Military Medical Science (Beijing, China). All mouse studies were approved by the Animal Ethics Committee of Tianjin Medical University. All animals were 6-8 weeks of age at the time of injection. PC3 cells, expressing luciferase or CNF1 or CNF1-C866S, were resuspended in 300 μl PBS (Biological Industries) and injected into the lateral tail vein of mice (2 × 10^6 cells/animal). 22Rv1-luci cells treated with CNF1 or CNF1-C866S (1 nMol/L for 12 h) were resuspended in 50% matrigel and injected into the prostate of mice (4 × 10^6 cells/animal).

Mice of both groups were imaged weekly using an IVIS Spectrum scanner (Caliper Life Sciences, Alameda, CA, USA). 200 μl of substrate D-luciferin (Promega Madison WI USA) (3.0 mg) in PBS was injected i.p. in each mouse 10 min prior to imaging. The bioluminescence images were quantified by measuring the total photons over the body and presented as photons/second /cm^2 /sr (sr denotes steradian).

**Immunohistochemistry (IHC)**

Murine lungs were fixed in 4% paraformaldehyde for 24 h and processed for paraffin embedding. Sections (5 μm) were used for hematoxylin and eosin staining and immunohistochemistry for HLA class I (HLA-A, 1:200, 15240-1-AP, Proteintech,
Chicago, IL, USA), p-PAK1 (Thr423) (1:10, #2601, Cell Signaling Technology) and MMP-9 (1:100, BA0573, BOSTER).

**RNA interference**

Double-stranded RNAs as siRNAs for targeted genes and Scrambled siRNA (siScr) were synthesized by GenePharma (Shanghai, China). The sequences (sense strand) of siRNAs are listed in Table S2. Specific gene knockdowns were assessed by western blotting. Transfection of siRNA was carried out using Lipofectamine 3000 (Invitrogen).

**Tissue microarray analysis**

The prostate cancer tissue microarray (PR1921a) containing 96 male specimens (8 normal prostate tissue, 8 adjacent normal prostate tissues, and 80 malignant tissues with grade II, II-III or III) was purchased from Alenabio (Xi'an, China). Staining was evaluated as described previously [22], and the values of staining intensity were determined by Image-Pro Plus software.

**Statistical analyses**

Data from three independent experiments are presented as the mean ± SD. The statistical significance of differences between groups was calculated using two-tailed student’s t-test or one-way analysis of variance using SPSS 22.0 software.

**Phylogenetic analysis**

The presence of cnf1 was found by screening the genome sequences of 63 UPEC strains used in our previous study [23]. A phylogenetic tree based on the alignments of combined protein sequences from CNF1 was constructed using maximum likelihood
in MEGA 5 with 1000 bootstrap experiments.
Results

CNF1 promotes the migration and invasion of prostate cancer cells in vitro

Recombinant CNF1 derived from UPEC strain 11 was purified and validated using mass-spectrography (Table S3). PC3 cells were treated with CNF1, LPS or the dialysis buffer as control and then subjected to a wound healing assay. CNF1 induced migration in a dose- and time-dependent manner (Figure 1A, B). Promotion of PC3 migration and invasion by CNF1 was also evaluated in a transwell assay (Figure 1C, D). We further validated the pro-migratory and pro-invasive effects of CNF1 on other androgen-dependent or -independent PCa cell lines (LNCaP, VCaP and 22Rv1) (Figure S1A, B). As CNF1 is a typical secretory bacterial protein, we treated PC3 cells with the supernatant from CNF1-overexpressing E. coli K12, which increased both the migration and invasion abilities of PC3 cells (Figure 1E, F).

It has been reported that cysteine 866 and histidine 881 are functional essential amino acid residues of CNF1 [24]. C866S mutation completely eliminated CNF1’s pro-migratory and pro-invasive effects, while H881Q partially blocked activity (Figure 1G, H and Figure S1C). Taken together, these results provide strong evidence that CNF1 has pro-migratory and pro-invasive activity on PCa cells.

CNF1 promotes the in vivo metastasis of prostate cancer cells

The effect of CNF1 on metastasis of PC3 cells was analyzed in vivo using a xenograft
mouse model. PC3 cells were transduced with constitutively expressed luciferase and the CNF1 functional domain (named CNF1c, AA 515 to 1014, the functional fragment previously reported [14]), or CNF1c-C866S, or a luciferase only control. The expression of luciferase, CNF1c and CNF1c-C866S was confirmed in the transduced cells. Overexpression of CNF1c protein but not CNF1c-C866S promoted migration and invasion (Figure S2A-C). Control or CNF1c-expressing or CNF1c-C866S-expressing PC3 cells were injected into the tail vein of NOD/SCID mice. Three weeks after injection, mice receiving the PC3 cells with CNF1c overexpression had a higher level of lung metastasis compared to mice receiving the PC3 cells with either CNF1c-C866S or control vector (Figure 2A and Figure S2D). Lung metastasis in mice receiving the CNF1c-overexpressing PC3 was identified by H&E staining and by IHC for HLA (Figure 2B, C).

Luciferase labeled 22Rv1 cells treated with CNF1 or CNF1-C866S were injected into the prostate of NOD/SCID mice. Seven weeks after injection, mice receiving 22Rv1-luci cells treated with CNF1 had a higher level of metastasis (Figure 2D and Figure S2E).

**CNF1 activates Rho GTPases in prostate cancer cells**

To determine whether CNF1 can enter PCa cells, we treated PC3 cells with CNF1 for 12 h and performed immunofluorescence (IF) for CNF1 protein. There was
accumulation of CNF1 protein in the cytoplasm (Figure 3A). We also verified the intracellular presence of CNF1 using western blotting (Figure 3B).

We examined the activation levels of the main three Rho-GTPase family members, (RhoA, Cdc42 and Rac1) induced by CNF1 using a pull down assay. RhoA, Cdc42 and Rac1 were activated in PC3 cells treated by CNF1; and among the three GTPases, CNF1’s affect was stronger on Cdc42 and Rac1 compared to RhoA (Figure 3C-E).

**CNF1 promotes the migration and invasion of prostate cancer cells through Cdc42**

We hypothesized that CNF1 promoted the motility and invasive properties of PCa cells by activating Rho GTPases, which regulate actin cytoskeletal re-arrangement [25]. We blocked the three GTPases using inhibitors (Figure S3A) and found that enhancement of motility and invasion by CNF1 was attenuated in a dose-dependent manner by inhibiting Cdc42, but not Rac1. Inhibition of RhoA reduced PC3 migration and invasion in both the CNF1 treated and control groups (Figure 4A-F).

Cdc42 expression was knocked down using siRNAs (Figure 4G, Figure S3B). The migration and invasion of Cdc42 knocked-down PC3 cells treated with CNF1 was significantly diminished compared to siScr control (Figure 4H, I). Two other siRNAs targeting different sites of Cdc42 were used to verify our observations (Figure S3C, D). RhoA and Rac1 were also knocked down using siRNA, which did not affect the
migration and invasion of PC3 cells promoted by CNF1 (Figure S3E-J).

The activation level of Cdc42 in the androgen-dependent cell line 22Rv1 was also up-regulated after treatment of CNF1 (Figure S3K). To determine the role of active Cdc42 in the migration and invasion of PCa cells, Cdc42 or constitutively active Cdc42 (CA-Cdc42, Q61E; Q61 was reported to be deamidated by CNF1 [17]) or dominant negative Cdc42 (DN-Cdc42, T17N) were transfected into PC3 (androgen-independent) or 22Rv1 (androgen-dependent) cells. PCa cells transfected with CA-Cdc42 had higher levels of active Cdc42 and their migration and invasion ability were significantly increased compared to PCa cells transfected with Cdc42 or DN-Cdc42 (Figure 4J-L, Figure S4A-C).

**Cdc42-mediated phosphorylation of PAK1 is essential for the enhancement of prostate cancer cell migration and invasion induced by CNF1**

Group I p21-activated kinase 1 (PAK1) is an important effector of the small GTPase Cdc42 [26], and acts as an important regulator of cytoskeletal dynamics and cell motility [27]. To determine pro-migratory and pro-invasive effects of CNF1 on PC3 cells, we blocked this pathway with the PAK1 inhibitor (IPA3) [28]. Exposure of CNF1-treated PC3 cells to IPA3 decreased their migration and invasion in a dose-dependent manner (Figure 5A, B), indicating that CNF1 promotes these activities through PAK1. Thr423 phosphorylation is required for full activation of
PAK1 [28] and we found elevated phosphorylation of PAK1 at Thr423 after treatment with CNF1 (Figure 5C). Elevated phosphorylation of PAK1 was also identified in 22Rv1 cells treated with CNF1 (Figure 5D).

To determine the role of PAK1 phosphorylation in the migration and invasion of PCa cells, PAK1 or constitutively active PAK1 (CA-PAK1, T423E) or dominant negative PAK1 (DN-PAK1, K299R) were transfected into PC3 and 22Rv1 cells. The migration and invasion ability of PCa cells transfected with CA-PAK1 were significantly increased compared to PCa cells transfected with PAK1 or DN-PAK1 (Figure 5E-G, Figure S5A-C).

As we identified that CNF1 mediates its activity, in part, through Cdc42, we next investigated whether PAK1 activation is directly mediated by Cdc42 activation. The Cdc42 inhibitor CID44216842 inhibited phosphorylation of PAK1 (Figure 5H), and increased PAK1 phosphorylation was found in PC3 and 22Rv1 cells transfected with CA-Cdc42 compared to those transfected with Cdc42 or DN-Cdc42 (Figure 4J, Figure S4A). These findings demonstrate that CNF1 activates Cdc42-PAK1 signaling to promote the migration and invasion of prostate cancer cells.

**CNF1 upregulates the expression of MMP-9 by activating PAK1**

Nearly every member of the matrix metalloproteinases (MMPs) family has been reported to be dysregulated in human cancers, with the gelatinases (MMP-2 and MMP-9) playing a pivotal role in degrading extra-cellular matrix (ECM) [29]. We explored whether the pro-invasive effect is associated with MMP-9 or MMP-2. CNF1
upregulated MMP-9, but had no effect on MMP-2 expression. PAK1 inhibition diminished the ability of CNF1 to upregulate MMP-9 (Figure 6A). Increased MMP9 was found in PC3 and 22Rv1 cells transfected with CA-PAK1 compared to PCa cells transfected with PAK1 or DN-PAK1 (Figure 5E, Figure S5A). These results demonstrate that CNF1 can upregulate the expression of MMP-9 by activating PAK1. Inhibition of Cdc42 also significantly reduced the expression of MMP-9, but not of MMP-2 (Figure 6B). The level of active Cdc42, PAK1 phosphorylation and MMP-9 expression were also upregulated in PC3 cells with CNF1c overexpression compared to those with CNF1c-C866S or the control vector (Figure S2F). These results demonstrate that CNF1 can drive migration and invasion of PCa cells through the Cdc42-PAK1-MMP-9 pathway in vitro.

To further validate the role for CNF1 in promoting PCa invasion through PAK1 and MMP-9, we performed IHC analysis of lung tissue from the experimental mice described previously. MMP-9 and phosphorylated PAK1 expression were present in pulmonary metastasis of mice injected by PC3 cells with CNF1c expression (Figure 6C). These results suggest a key role for the Cdc42-PAK1-MMP-9 signaling axis in CNF1-induced PCa aggressiveness in vivo.

Activation of PAK1 is positively correlated with advanced human prostate cancer

The expression of phosphorylated PAK1 was analyzed by IHC using a human tissue array containing 96 samples, which include 80 PCa tissues with grade II, II-III, or III. The percentage of samples with phosphorylated PAK1 staining in malignant tissues
was higher than those in normal and adjacent normal tissues and was positively correlated with the histological grades of PCa (Figure 6D, E). We also found that the levels of phosphorylated PAK1 were strongly correlated with PCa grades (Figure 6F), and the positive percentage of samples with strong staining was higher in grade III and II-III than in grade II (Figure 6G). These results indicate that PAK1 activation is correlated with PCa advanced grades.

**CNF1 derived from other UPECs has similar pro-migratory and pro-invasive effects on prostate cancer cells**

We found 11 of 63 UPEC strains with available genome sequences included the *cnf1* gene. The 11 CNF1 proteins were separated into two groups, with two different amino acids (N666T, V1001A) in the segment of 515-1014 (Figure S6A). We purified another recombinant CNF1 derived from the UPEC strain 1, which belongs to a different UPEC group than the UPEC strain 11. Consistent with the results obtained from the UPEC strain 11-derived CNF1, UPEC strain 1-derived CNF1 also promoted the migration and invasion of PC3 cells (Figure S6B, C). Additionally, we detected the effects of Cdc42, Rac1, RhoA, and PAK1 inhibitors on strain 1-derived CNF1-induced cell migration and invasion (Figure S6D, E). The changes of MMP-9 expression and PAK1 phosphorylation level induced by CNF1 (strain 1) were also examined using western blotting (Figure S6F).

Three UPEC strain 11-derived CNF1 mutants: N666T, V1001A and double mutant were created. Wildtype and mutant CNF1-overexpressed *E. coli* K12 were used to perform phenotype experiments, and no obvious difference was observed on PC3 cell
migration and invasion (Figure S6G-I). These findings demonstrate that CNF1 derived from other UPECs has similar pro-migratory and pro-invasive effects on prostate cancer cells and that residues 666 and 1001 do not influence CNF1 activity.
Discussion

In this study, we identified that CNF1 secreted by UPEC could accelerate PCa progression through activating the Cdc42-PAK1 signaling axis (Figure S7). Almost 20% of all cancers are associated with microbial infection [30], and certain cancer types are promoted by bacteria. Helicobacter pylori is a prime example that bacterial pathogens can drive carcinogenesis, and has been classified as a carcinogen for gastric cancer by the International Agency for Research on Cancer (IARC) [31,32]. Other pathogenic bacteria such as Salmonella enterica, Borrelia burgdorferi, Chlamydia psittaci and Staphylococcus aureus have been reported to be associated with gallbladder cancer and certain kinds of lymphomas [33-37]. A few bacterial virulence factors have been identified to promote cancer by interacting with human signaling pathways, such as CagA and VacA of H. pylori and SEA of S. aureus [36,38]. The possible roles for many other bacterial toxins on cancer development and progression remain to be clarified.

Cdc42 expression is upregulated in many kinds of cancers such as breast, colorectal and ovarian cancer [39,40]. The role of Cdc42 in prostate cancer is rarely reported. The p21-activated kinases (PAKs) are overexpressed and activated in many human cancers and are positively correlated with advanced grades and decreased survival, and PAK1 is one of the best characterized PAKs dysregulated in cancers [41]. PAK1 upregulates MMP expression in breast cancer cells [42]. Higher expression of PAK1 was found in invasive PCa cells compared to non-invasive PCa cells, and inhibition of PAK1 impaired PC3 cell migration [43]. It was suggested that this effect was caused
by high expression of MMP-9 and low expression of TGFβ regulated by PAK1 [43]. In our study, CNF1 increased the phosphorylation of PAK1 by activating Cdc42, and then upregulated the expression of MMP-9. Upregulation of active PAK1 correlated with advanced-grade PCa using clinical human PCa samples, indicating that active PAK1 is a possible marker, although further experiments are required.

Only UPEC strains CP1 or CP9 have been used to infect the prostate in mouse or rat models in previous reports [11,12,44]. In our study, UPEC strain 1 or 11 cannot successfully infect the prostate of NOD/SCID mice and C57BL/6J mice, indicating that UPEC strains used for prostate infection in mouse models are very limited. CNF1 has been reported to enhance inflammation in bladder and prostate [44,45], and we also found that bladder inflammation caused by the CNF1 overexpressing K12 stain was greater than that caused by the CNF1 C866S overexpressing K12 stain and the K12 control strain (data not shown). Therefore, in addition to migratory and invasive activity of PCa cells promoted by CNF1, CNF1 inducing inflammation may also promote PCa progression, which needs further studies.

**Acknowledgements**

This study was supported by grants from the National Natural Science Foundation of China (NSFC) Programs (31670071, 81672740, 31270016), the State Key Laboratory of Medicinal Chemical Biology (201601009). The authors thank Dr. Antoni Rozalski and Agata Palusiak from University of Lodz for supplying UPEC strains, and members of Dr. Wang’s and Dr. Yao’s laboratory for helpful technical assistance.
Author contribution statement

QW designed the study, YG, JW, ZZ and KZ performed the majority of experiments, HW and JL performed parts of cell and animal experiments. QW, YG, ZZ and ZY analyzed the data and wrote the paper. Experimental design assistance and manuscript revision were provided by EK. All authors discussed the data, reviewed and approved the manuscript.

Migration ability in the wound healing assay of PC3 cells treated with recombinant CNF1 protein in different doses, dialysis buffer and LPS as the control. (B) Time dependent migration assay of CNF1 (1 nMol/L) on PC3 cells. (C) and (D) Transwell based migration and invasion assays of PC3 cells treated with 1 nMol/L CNF1. (E) and (F) Migration and invasion assays of PC3 cells treated with supernatant from overexpressed CNF1 or vector in E. coli K12. (G) and (H) Migration and invasion assays of PC3 cells treated with supernatant from different strains overexpressing wild type CNF1 and CNF1 mutant C866S or H881Q (blank vector as the negative control). Bar graphs represent data from three independent assays (mean ± SD. **p < 0.01; one-way ANOVA (A-D, G and H) or Student’s t test (E and F). Scale bar, 50 μm.

Figure 2. CNF1 promotes the in vivo metastasis of prostate cancer cells in a xenograft mouse model. (A) Luciferase labeled PC3 cells without CNF1 expression (N = 9), with CNF1 expression (N = 12) or with CNF1-C866S expression (N = 7) (2 × 10⁶) were injected into NOD/SCID mice via the lateral tail vein, and bioluminescence imaging of live mice was performed at the third week. (B) H&E staining of lung tissue showing significant metastasis in the CNF1 group (magnification 100× and 400×) and normal tissue in the control group. (C) Immunohistochemically analysis of murine lung with PC3 cells staining HLA-A with a specific antibody (magnification 100× and 400×). (D) Luciferase labeled 22Rv1 cells treated with CNF1 (N = 4), or CNF1-C866S (N = 6) (4 × 10⁶) were injected into the prostate of NOD/SCID mice,
and bioluminescence imaging of live mice was performed at the seventh week.

Figure 3. CNF1 activates Rho GTPases in PCa cells. (A) Representative immunofluorescence images of PC3 cells treated with recombinant CNF1 protein (1 nMol/L) for 12 hours. Blue, nucleus; Green, CNF1. Scale bar, 50 μm. (B) Western blotting analysis of CNF1 protein in PC3 cells cultured with CNF1 recombinant protein (1 nMol/L) for 3 and 6 hours, β-actin as the loading control. (C–E) Western blotting analysis of activated Rho GTPases. RhoA, Cdc42 and Rac1 in PC3 cells (treated with recombinant CNF1 protein (1 nMol/L) or dialysis buffer for 12 hours) after immunoprecipitation with GTP-pull down assays using specific antibodies.

Figure 4. CNF1 promotes the migration and invasion of PCa cells through Cdc42. (A–C) Transwell migration assays of PC3 cells treated with specific inhibitors of RhoA (CCG-1423), Cdc42 (CID44216842) and Rac1 (EHT 1864) in different concentrations and 1 nMol/L CNF1 (or dialysis buffer). Line graphs represent data from 3 independent assays. (D–F) Invasion assays of PC3 cells treated with specific inhibitors for Rho GTPases with CNF1 protein. (G) Western blotting analysis of PC3 cells treated with siRNAs targeting Cdc42 and scrambled non-targeting control siRNA. (H) and (I) Migration and invasion assays of CNF1 treated PC3 cells after being transfected with Cdc42 or scramble siRNAs. (J) Western blotting analysis of PC3 cells transfected with Vector, Cdc42, constitutively active Cdc42 or dominant negative Cdc42. (K) and (L) Migration and invasion assays of PC3 cells transfected
with Vector, Cdc42, constitutively active Cdc42 or dominant negative Cdc42. Bar graphs represent data from three independent assays (mean ± SD. *p < 0.05. **p < 0.01; one-way ANOVA (A to F, H, I, K and L). Scale bar, 50 μm.

Figure 5. Cdc42-mediated phosphorylation of PAK1 is essential for the enhancement of PCa cell migration and invasion by CNF1. (A) Migration assays of PC3 cells cultured with the PAK1 inhibitor IPA3 in different concentrations accompanied with CNF1 protein or dialysis buffer. Line graph represents data from three independent experiments. (B) Invasion assays of PC3 cells under the treatment of IPA3 and CNF1, DMSO and dialysis buffer as the specific control. The bar graph represents data from three independent assays. (C) Western blotting analysis of activated PAK1 (phosphorylated on Thr423) and total PAK1 in PC3 cells after the treatment with CNF1 protein (1 nMol/L) at 3-12 hours. (D) Western blotting analysis of 22Rv1 cells treated with CNF1 or dialysis buffer. (E) Western blotting analysis of PC3 cells transfected with Vector, PAK1, constitutively active PAK1 or dominant negative PAK1. (F) and (G) Migration and invasion assays of PC3 cells transfected with Vector, PAK1, constitutively active PAK1 or dominant negative PAK1. (H) Analysis of activated PAK1 and total PAK1 of PC3 cells under the treatment of the Cdc42 inhibitor CID44216842 and CNF1 protein, with DMSO and dialysis buffer as the control. Bar graphs represents data from three independent assays (mean ± SD. *p < 0.05. **p < 0.01; one-way ANOVA (A, B, F, G). Scale bar, 50 μm.
Figure 6. CNF1 upregulates the expression of MMP9 through Cdc42-PAK1 axis and active PAK1 are positively correlated with advanced-grade PCa. (A) and (B) Western blotting analysis of metastasis associated metalloproteinases MMP-9 and MMP-2 in PC3 cells treated with the PAK1 inhibitor IPA3 or the Cdc42 inhibitor CID44216842 with CNF1 protein or dialysis buffer. (C) IHC of murine lung specimens from CNF1-overexpressed PC3 xenograft metastasis model for MMP-9 and activated PAK1 (magnification 100× and 400×). (D) IHC analysis of PAK1 phosphorylation using human PCa tissue microarray. Representative images (magnification, 200×) from normal prostate tissues, adjacent normal prostate tissues, and malignant prostate tissues with grade II, II-III or III are shown. (E) The percentage of samples with positively stained p-PAK1. n indicates the sample size in different groups. (F) Mean intensity of staining determined by Image-Pro Plus software and presented with box plots. (G) The percentage of samples with high (orange), medium (dark gray) and weak (light gray) staining of p-PAK1 in positively stained samples with different grades. Data are mean ± SD. *p < 0.05. **p < 0.01; one-way ANOVA (A, B, F).
