Article type : Original Contribution

Return Visit Admissions May Not Indicate Quality of Emergency Department Care for Children
Abstract

Objective: To test the hypothesis that in-hospital outcomes are worse among children admitted during a return ED visit than among those admitted during an index ED visit.

Methods: Retrospective analysis of ED visits by children age 0-17 to hospitals in Florida and New York in 2013. Children hospitalized during an ED return visit within 7 days were classified as “ED return admissions” (discharged at ED index visit and admitted at return visit) or “readmissions” (admission at both ED index and return visits). In-hospital outcomes for ED return admissions and readmissions were compared to “index admissions without return admission” (admitted at ED index visit without 7-day return visit admission).

Results: Among 1,886,053 index ED visits to 321 hospitals, 75,437 were index admissions without return admission, 7,561 were ED return admissions and 1,333 were readmissions. ED return admissions had lower intensive care unit (ICU) admission rates (11.0% versus 13.6%; adjusted odds ratio (AOR) 0.78, 95% confidence interval (CI) 0.71-0.85), longer length of stay (LOS, 3.51 vs. 3.38 days; difference 0.13 days; incidence rate ratio (IRR) 1.04; 95% CI 1.02-1.07), but no difference in mean hospital costs ((\$7138 vs. \$7331; difference -\$193; 95% CI -\$479 to 93) compared to index admissions without return admission.

Conclusions: Compared with children who experienced index admissions without return admission, children who are initially discharged from the ED who then have a return visit

This is the author manuscript accepted for publication and has undergone full peer review but has not been through the copyediting, typesetting, pagination and proofreading process, which may lead to differences between this version and the [Version of Record](#). 28 admission had lower severity and similar cost, suggesting that ED return visit admissions do not
29 involve worse outcomes than do index admissions.

30 **Introduction**

31 Return visits to the emergency department (ED) are common among US children, with
32 72-hour return rates of 2.5% - 5.2% previously documented.¹ As a quality measure, ED return
33 visits align conceptually with two of the National Quality Strategy's six priority areas:² safety of
34 care—as a measure of harm caused by inadequate ED diagnosis or management³—and
35 coordination of care—as a measure of deficient ED-to-outpatient transition of care.^{4,5} These
36 visits have also been recommended as a measure of the safety and quality of ED care by several
37 systematic, modified-Delphi process reviews.⁶⁻¹⁰ This recommendation is based on the premise
38 that return visits may signal lower quality ED care during the index visit.⁶⁻¹⁰ If preventable
39 through improved care at an index ED visit, return visits present an opportunity to reduce costs,
40 target medical errors and improve patient satisfaction.^{1,11-13} Two previous studies have measured
41 the relative clinical severity and resource utilization of ED return visits but did not focus
42 specifically on children.^{14,15} Both found that ED return visits had lower illness severity and
43 resource use than the comparison group, suggesting that ED return visits may not reflect poor
44 quality of care during the index ED visit.

45 Children represent a unique population to consider given differences in the clinical
46 conditions for which they are commonly cared for in the ED and differences in how pediatric
47 care is delivered. Previous work has challenged the construct validity of return visits as a
48 measure of ED care quality for children—these include chart review studies that find the
49 majority of ED return visits and ED return admissions are due to progression of illness or
50 patient's noncompliance with care rather than poor quality of initial ED care,¹⁶⁻¹⁸ and secondary
51 data analyses demonstrating the poor reliability of ED return visits as a performance measure
52 compared with other ED process measures.¹⁹⁻²¹ Other studies have challenged the common
53 practice of tracking only same-hospital ED return visits—these studies show that 12-32% of 72-
54 hour return visits among adults and all-ages populations do not occur at the same hospital as the
55 index visit.²²⁻²⁴

56 The primary objective of our study was to assess ED return visits as a measure of the
57 quality of ED care for children by comparing in-hospital clinical outcomes and resource use
58 among those admitted during an ED return visit, readmissions and index admissions without

59 return admission. Our secondary objective was to measure how well same-hospital ED return
60 visits, return admissions and readmissions correlate with all-hospital return visits among
61 children.

62 63 **Methods**

64 *Study Design*

65 We performed a retrospective analysis of ED visits in a publically available set of datasets. This
66 study was considered not human subjects research by the Colorado Multiple Institutional Review
67 Board because of its use of publicly available datasets.

68 69 *Study Setting and Population*

70 We performed a retrospective analysis of ED visits by children age 0-17 to hospitals in
71 Florida and New York in 2013 using data from the Agency for Healthcare Research and Quality,
72 Healthcare Cost and Utilization Project (HCUP), as these are the two largest state databases with
73 shared ED and inpatient patient-level identifier (HCUP's VisitLink variable) permitting tracking
74 patients temporally through both ED and inpatient visits. Hospital discharge records from the
75 State Inpatient Database (SID) were linked with ED discharge records from the State Emergency
76 Department Database (SEDD).

77 Each SID includes encounter-level data for all hospitalizations regardless of admission
78 source, whereas the SEDD contains similar information on treat-and-release ED visits (i.e.,
79 discharges). To identify admissions that originated in the ED, the dataset was limited to inpatient
80 records in the SID with evidence of ED-level services, including ED revenue code, ED CPT
81 code, ED charge or ED source of admission. We then excluded records for elective or scheduled
82 admissions, admissions for deliveries, neonatal admissions from a source other than the ED, and
83 records for transfers in-from or out-to another short-term hospital. Once admissions that
84 originated in the ED were identified, they were combined with ED discharge records in the
85 SEDD, creating a complete dataset of all ED visits within the year.

86 87 *Study Protocol*

88 Patient identifiers and time variables were used to track return visits across the SID and
89 SEDD. To characterize ED admissions into 3 return visit cohorts, we first identified distinct

90 episodes of emergency care, which included an index visit plus any 7-day return visit. An index
91 visit was defined as the first ED visit for a unique patient or any successive ED visits where the
92 patient had no prior ED visit or hospital admission in the preceding 30 days. Therefore, one
93 patient may have multiple episodes available for analysis. We excluded visits in which the
94 patient died (n=390) or left against medical advice (n=19,783) during their index visit, ED visits
95 in which the patient was transferred out of the ED to another hospital (because we could not
96 ascertain whether the patient was subsequently admitted to another hospital, n=20,559), records
97 missing a return visit variable (n=986,922) and index visits in the months of December and
98 January because it was not possible to assess prior visits and return visits; (New York only;
99 Florida does not specify visit month; n=218,820). The remaining index ED visits were followed
100 for any ED return visits within 7 days.²⁵

101 Patients with the main exposure--a 7-day ED return visit that resulted in hospital
102 admission--were stratified into two groups based on the outcome of their previous index ED
103 visit: "ED return admissions" (patients discharged from the ED at their index visit with hospital
104 admission during their 7-day return visit) and "readmissions" (patients admitted to the hospital
105 on both their index visit and 7-day ED return visit). For consistency of comparison, we limited
106 our analysis to the first return visit after an index visit. For patients in the readmission cohort
107 with more than one readmission, only initial readmission outcomes were assessed. We compared
108 in-hospital clinical outcomes and resource use for patients in the exposure group—those with ED
109 return admissions or readmissions--versus outcomes for the control group: patients admitted
110 during their index visit who did not have a 7-day return inpatient visit ("index admissions
111 without return admission"). Designation of this as our control group assumes that this group
112 approximates the average inpatient admission because most children who are hospitalized on an
113 index ED visit do not have a return visit. Identification of the 3 return visit cohorts is shown in
114 Figure 1.

115 116 *Measures:*

117 We measured two clinical outcomes—in-hospital mortality and ICU admission—and two
118 measures of inpatient resource use—total hospital costs and length of stay (LOS). Studies of ED
119 return visits for children have studied timeframes from 48 hours to 3 months, with 72 hours the
120 most common window.^{24,26,27} We selected 7 days as the primary timeframe but included a

121 sensitivity analysis of three additional timeframes—72 hours, 14 days and 30 days--for two
122 reasons: (1) based on time to event analyses of ED return visits that showed a pattern of rapid
123 accrual of ED return visits up to 30 days,^{25,28} and, (2) because 30 days is the most common
124 window for measuring pediatric hospital readmissions, one of the outcomes in our analysis.^{29,30}
125 Patients who died in the ED on a return visit were counted as having died in hospital. ICU
126 admission was chosen to capture patients with a severe clinical course and was identified by
127 critical care UB-92 revenue codes (0200-0209, 0210-0219). Total costs were assessed by
128 applying HCUP cost-to-charge ratios provided for the SID.

129

130 *Data Analysis*

131 Statistical analyses were performed using Stata version 13 (StataCorp). To evaluate
132 adjusted differences in outcomes and resource utilization between the return visit cohorts, a
133 series of multivariable generalized linear models were developed controlling for known risk
134 factors for recurrent ED utilization in children: age, sex, race, complex chronic conditions³¹ and
135 primary payer.^{1,32,33} We utilized the logit-link for the dichotomous outcomes of mortality and
136 ICU admission. Both total costs and LOS were highly right-skewed. For the analysis of total
137 costs we applied a log-link with gamma distribution and applied a negative binomial distribution
138 for LOS. Regression diagnostics were performed to assess for model fit. Patients who died
139 during their admission were excluded from the modeling of costs and LOS.³⁰ To account for
140 within-hospital correlation of patient outcomes, clustered standard errors were utilized. To avoid
141 bias from low volume hospitals we excluded hospitals with <25 pediatric admissions in 2013.²⁴

142 **Results**

143 *Return Visit Rates*

144 Among the 1,886,053 index ED visits to 321 hospitals experienced by 1,442,154 unique
145 pediatric patients, 1,809,283 (95.9%) were discharged and, of these, 106,221 (5.9%) had an ED
146 return visit and 7,561 (0.71% of all discharged patients and 7.1% of all ED return visits) had an
147 ED return admission. Of the 76,770 (4.1%) index ED visit admissions, 72,432 (94.3%) did not
148 have a 7-day ED return visit (included in the index admission without return admission cohort).
149 Of the 4,338 index admissions with an ED return visit, 1,333 (30.7%) were readmitted (the

150 readmissions cohort) and 3,005 (69.3%) were not readmitted (included in the index admission
151 without return admission cohort). (Figure 1).

152 Of the 106,211 patients with an ED return visit, 78.4% returned to the same ED as the
153 index visit. Of those returning to the same ED, 5.8% were admitted; of those returning to another
154 ED, 11.9% were admitted. In contrast to return visit admissions, of the 4,338 ED return visits of
155 patients discharged from a hospital after an inpatient stay, 70.6% returned to the same hospital's
156 ED. Of those returning to the same hospital, 38.9% were admitted and of those returning to
157 another hospital's ED, 11.1% were admitted. Overall, 21.6% of return ED visits, 36.2% of return
158 visit admissions and 10.6% of readmissions occurred at another hospital. (Figure 1)

159 In sensitivity analyses, 2.5%, 8.1% and 12.1% of patients initially discharged had an ED
160 return visit in 72 hours, 14 days and 30 days, respectively; of these, 7.5%, 6.3% and 5.4% were
161 admitted. Among those initially admitted, 2.2%, 8.3% and 13.1% returned within 72 hours, 14
162 days and 30 days, and of these 28.6%, 32.5% and 32.8% were readmitted.

163 We compared patients in the study cohort to those excluded from the study cohort
164 because of missing revisit linking variables, based on the characteristics from Table 1. The only
165 significant differences were that excluded patients were younger (5.3 vs. 7.3 years), less likely to
166 have any comorbid condition (3.3% vs 6.8%), more likely to be uninsured (4.4% vs. 3.5%) and
167 less likely to have Medicaid insurance (59.8% vs 64.9%) than those in the analytic cohort.

168 *Characteristics of Cohorts*

169 Table 1 lists the characteristics of our study cohorts. Patients who were high utilizers of
170 the ED (≥ 4 visits/year) were more likely to experience an ED return visit and comprised 22.6%
171 of the total sample, but accounted for 21.4% of ED return admissions and 28.2% of
172 readmissions.³² Patients who experienced any return visit with admission (either ED return
173 admission or readmission) were more likely to be female and have public insurance compared
174 with index admissions without return admission. In addition, patients in the readmission cohort
175 had substantially more comorbid conditions than those in ED return admission and the index
176 admission without return admission cohorts (18.8% vs. 4.2% vs. 5.7%, respectively).

177 Among patients with a 7-day return visit, the most common diagnoses—grouped using
178 the Healthcare Cost and Utilization Project's Clinical Classification Software³⁴—were other

179 aftercare (mostly post-procedure care for incisions and other openings), upper respiratory
180 infections, fever of unknown origin and viral infections. (Table 2) Of those hospitalized on their
181 return visit, the most common conditions were pneumonia, asthma, acute bronchitis and skin and
182 subcutaneous tissue infections. (Table 2) The most common of these, pneumonia, totaled only
183 721 hospitalizations, and thus we were precluded from diagnosis-specific analyses by small
184 sample within each diagnosis.

185 186 *Outcomes by Cohort*

187 Results of our multivariable regression are presented in Tables 3 and 4. After adjusting
188 for patient case-mix, when compared to index admissions without return admission, ED return
189 admissions had lower intensive care unit (ICU) admission rates (11.0% versus 13.6%; adjusted
190 odds ratio (AOR) 0.78, 95% confidence interval (CI) 0.71-0.85), slightly longer length of stay
191 (LOS, 3.51 vs. 3.38 days; difference 0.13 days; incidence rate ratio (IRR) 1.04; 95% CI 1.02-
192 1.07), and similar mean hospital costs ((\$7138 vs. \$7331; difference -\$193; 95% CI -\$479 to
193 \$93). In contrast, when compared to index admissions without return admission, readmissions
194 had similar rates of ICU admission 12.9% versus 13.6% (AOR 0.94, 95% 95% CI 0.82-1.08),
195 similar costs (\$8037 vs. \$7331; difference \$706; 95% CI -\$17 to \$1429) and longer LOS (4.18
196 vs. 3.38 days; difference of 0.80 days; IRR 1.24; 95% CI 1.15-1.33).

197
198 In-hospital mortality was similar across the 3 return visit cohorts with wide adjusted odds
199 ratio CI reflecting the rarity of death among hospitalized children.³⁵ We found overall
200 associations among clinical outcomes and inpatient resource use to be similar for patients
201 returning within 72 hours, 14 days and 30 days in our sensitivity analyses (Tables 3 and 4). In
202 adjusted analyses using the three timeframes, when compared to index admissions without return
203 admission, ED return admissions had lower rates of ICU admission and longer LOS, without
204 difference in mortality. In contrast to the analyses using the shorter timeframes, at the 30-day
205 timeframe we found a small difference in inpatient costs of ED return admissions when
206 compared to index admission (\$7000 vs. \$7283; difference -\$283; 95% CI -\$509- -\$58).

207 208 **Discussion**

209 To our knowledge, this is the first study to assess in-hospital outcomes among children
210 experiencing an ED return visit admission. Patients who are discharged from the ED and are
211 hospitalized on a return visit are a less sick cohort relative to other admissions (both patients who
212 were admitted on the initial visit and those who were admitted both on the initial and repeat) We
213 found that patients who experienced an ED return admission had lower rates of ICU admission
214 compared to the index admissions without return admission cohort. While this group also had
215 slightly longer LOS, total hospital costs were similar between the groups, suggesting that the
216 small LOS difference is unlikely to be clinically significant. In contrast, readmissions among
217 patients with ED return visits had similar clinical outcomes and slightly longer LOS during the
218 readmission compared to the index admissions without return admission cohort. In hospital
219 mortality was similar across the 3 cohorts. Results were largely consistent for patients returning
220 to the ED within 72 hours, 14 and 30 days of their initial ED visit. In this large dataset, we were
221 unable to detect evidence that return visit admissions are associated with an increased need for
222 ICU resources or increased hospital costs. These findings suggest that ED return admissions for
223 children may not adequately discriminate among children with high versus low quality of care
224 delivered during an ED visit in hospital administrative datasets.

225 Numerous studies have challenged the construct validity of ED return visits and return
226 visit admissions as measures of ED care quality, including three studies of adults or all-ages
227 populations that, like our study, measured the clinical severity and resource utilization of ED
228 return visits.^{14,15,24} Of these three studies, our findings most closely approximate those of a recent
229 study that found that return ED admissions in adults, when compared with index admissions, had
230 lower in-hospital mortality, ICU admission rates, and in-hospital costs and LOS.¹⁵ Our current
231 study differs from this adult study in that we found no difference in mortality reflecting the rarity
232 of death among children in the ED (0.03%)³⁶ and hospitalized children (0.39%).³⁵ The adult
233 study also found that patients with ED return admissions had slightly longer LOS, despite having
234 lower total costs. In contrast, we find no difference in costs, likely because our study was
235 underpowered to examine this outcome. One explanation for this may be that patients with ED
236 return admissions are kept in the hospital longer because of the largely unbilled resources used to
237 address social factors, despite being less sick than index admissions without return
238 admission.^{1,32,33} The other two studies compared severity and ED resource use in ED return visits
239 to index ED visits. Both found lower severity in ED return visits when compared to index ED

240 visits, although one found 18% higher 30-day ED visit costs albeit 30% lower 3-day costs for
241 those with return visits,²⁴ and the other found lower resource use among those with return
242 visits.¹⁴

243 A major reason ED return visits have been suggested as a quality measure is that they are
244 presumed to reflect a population of inappropriate discharges from the ED, such as patients who
245 had potential errors in diagnosis or disposition made during their ED visit. This may be
246 especially true if the patient is sick enough to require hospitalization on their return visit. In fact,
247 our data show that after age, sex, and comorbidity adjustment, these patients have similar
248 outcomes to patients admitted on an index visit who do not have a return visit.

249 Our study complements the findings of prior studies that have attempted to assess the
250 quality of care leading to a ED return visit and found the majority of ED return visits were
251 related to *patient factors* such as noncompliance with ED discharge instructions, *illness factors*
252 including progression of the condition diagnosed at the index ED visit and *healthcare*
253 *environment factors* including poor access to post-discharge care, with a small minority of return
254 visits related to poor quality of ED care or unsafe discharge practices.^{16,17} The most common
255 diagnoses previously reported at ED return visits—fever, respiratory infections, and
256 gastroenteritis—are all self-limited acute medical conditions commonly treated in outpatient as
257 well as ED settings, and thus appropriate for a trial of outpatient management. Our findings are
258 also consistent with pediatric studies that have found poor reliability of ED return visits as a
259 performance measure in its lack of correlation with other ED process measures such as rate of
260 radiographic study utilization and physician treatment time.¹⁹⁻²¹

261 Our study also adds to prior work by capturing return visits outside the index hospital for
262 ED return visits, ED return admissions and readmissions through the ED. Focusing solely on
263 return visits to the same hospital would have missed 21.6% of return ED visits, 36.2% of return
264 visit admissions and 10.6% of readmissions through the ED. Our findings are similar to the one
265 pediatric study that captured all-hospital readmissions and found 13.9% occurred at other
266 hospitals.³⁷ Although adult population studies used a shorter, 72-hour timeframe, they found
267 similar proportions of return visits returning to other hospitals: 12-32%.²²⁻²⁴ It is likely that using
268 only same-hospital return visit data will under-estimate the actual, all-hospital return rate,
269 suggesting that same-hospital return visit data may not be a reliable comparative quality
270 measure.²³

271 Patients discharged from the ED who return to another ED were more likely to be
272 admitted than those returning to the same ED. Without the records from the ED for the index
273 visit, the other ED's providers may lower their admission threshold solely based on the recurrent
274 visit. Return visits that occur at another hospital may have special clinical and financial
275 implications as they raise the potential for fragmentation of care and the associated risk of
276 duplication of services and other care coordination concerns.³⁸

277 Thus, our findings support those of other studies in demonstrating ED return visit
278 admissions do not reflect poor quality of ED care. Were we to base performance measures on ED
279 return visits or return admissions, especially if tied to reimbursement penalties, we run the risk of
280 penalizing hospitals for factors largely outside their control. This is likely to disproportionately
281 penalize hospitals serving vulnerable populations, particularly patients with limited access to
282 healthcare elsewhere.^{32,39} Another potential unintended consequence is that penalizing ED return
283 visits might encourage ED physicians to admit more patients to reduce return visits. Despite the
284 lack of evidence supporting ED return visits and ED return admissions as measures of ED care
285 quality, our findings do not challenge the potential value of these measures as internal quality
286 assurance screening tools for identifying potential quality issues.²⁶

287

288 **Limitations**

289 This study should be interpreted with the following limitations. First, the retrospective
290 analysis of a secondary data set was limited the hospital-based outcomes that could be measured
291 that were relevant to our all-condition focus. For example, we did not study condition-specific
292 indicators, such as occurrence of specific procedures (e.g., appendectomy) or diagnoses (e.g.,
293 meningitis) that could have indicated diagnoses missed during the index visit. Thus, although all-
294 condition return visits do not accurately reflect deficits in ED care quality, condition-specific
295 measures are likely to have better construct validity and would need to be explored in future
296 studies. Second, our conclusions are predicated, in part, on the assumption that poor quality of
297 care during an ED visit will be reflected in disease severity sufficiently worsened to result in
298 increased probability of admission to an ICU or in increased hospital costs on a return ED visit
299 admission when compared to an index admission. However, it is only in some cases of poor ED
300 care that one would expect deterioration in the clinical condition of the patient sufficient to
301 require admission to the ICU or that would result in increased hospital length of stay. This

302 assumption may have resulted in type 1 error. Third, the hospital-based data sets did not permit
303 us to assess mortality among children who died outside the hospital. However, death outside the
304 hospital shortly after ED discharge is rare among children, occurring in less than 0.02% of
305 discharges, and thus this likely did not bias our findings.⁴⁰ Fourth, there may be additional
306 unmeasured confounders that accounts for differences in outcomes observed between groups that
307 were not adjusted for. Some of these additional patient factors, such as medical severity
308 indicators and hospital factors are likely to account for differences among return visit cohorts and
309 would need to be explored in future studies. Fifth, our methods may have led us to underestimate
310 ED return visits. We excluded return visits after the initial ED return visit, direct admissions and
311 visits for patients transferred in or transferred out, recognizing that some may be return visits.
312 Limited evidence suggests including these additional visits would not have changed the direction
313 of our findings.³² Sixth, we had to exclude ED visits in the months of January and December to
314 ensure accurate accounting of ED return visits. This may have induced bias into our results due
315 to seasonal differences in ED clinical presentations. Finally, our cost estimates only included
316 hospital costs and did not include the other costs associated with a return visit to the hospital,
317 including missed wages.

318

319 **Conclusion**

320 Compared with children who experienced index admissions without return admission,
321 those initially discharged who then experienced a ED return visit within 7 days that resulted in
322 admission had similar outcomes, suggesting that admissions associated with ED return visits
323 may not reflect poor quality emergency care for children.

Table 3. Multivariable regression results for ED return admissions and readmissions*

	Adjusted Odds Ratio (95% CI)			Cost Difference (Range), \$^A
	In-Hospital Mortality	ICU Admission	LOS IRR (95% CI)	
≤ 72 hours				
ED Return Admission vs. Index Admission without Return Admission	0.87 (0.45-1.67)	0.77 (0.71-0.85)**	1.03 (1.00-1.06)	-309 (-628 to 10)
Readmission vs. Index Admission without Return Admission	0.74 (0.24-2.28)	0.91 (0.77-1.09)	1.15 (1.07-1.23)**	46 (-450 to 544)
≤ 7 days				
ED Return Admission vs. Index Admission without Return Admission	0.83 (0.43-1.58)	0.78 (0.71-0.85)**	1.04 (1.02-1.07)**	-193 (-479 to 93)
Readmission vs. Index Admission without Return Admission	0.80 (.26-2.41)	0.94 (0.82-1.08)	1.24 (1.15-1.33)**	706 (-17 to 1429)

≤ 14 days				
ED Return Admission vs. Index Admission without Return Admission	0.75 (0.42-1.36)	0.78 (0.72-0.83)**	1.04 (1.02-1.07)**	-212 (-468 to 44)
Readmission vs. Index Admission without Return Admission	0.67 (0.3-1.50)	0.97 (0.84-1.11)	1.26 (1.18-1.34)**	489 (-87 to 1067)
≤ 30 days				
ED Return Admission vs. Index Admission without Return Admission	0.62 (0.36-1.07)	0.82 (0.76-0.87)**	1.04 (1.02-1.07)**	-283 (-509 to -58)**
Readmission vs. Index Admission without Return Admission	0.75 (0.43-1.30)	1.00 (0.87-1.14)	1.24 (1.18-1.30)**	499 (22 to 975)**

*All models adjusted for age, sex, race, Feudtner comorbidities, primary payer. Control group: index admissions without a return visit admission.

**These outcome differences are statistically significant.

^Hospital costs reported in mean difference in whole dollars rather than the exponentiated coefficient for ease of interpretation.

Abbreviations: CI = confidence interval; ICU = intensive care unit; LOS = length-of-stay; IRR = incidence rate ratio

Table 4. Adjusted in-hospital mortality, ICU admission, length of stay, and inpatient costs (95% CI) for ED return admissions and readmissions*

		<i>Control</i>	<i>Exposure: Return Visit Admission</i>	
		Index Admission without Return Admission	ED Return Admission	Readmission
≤ 72 hours	In-Hospital Mortality	0.20% (0.17-0.25)	0.18% (0.07-0.29)	0.16% (0.00-0.32)
	ICU Admission	13.5% (11.6-15.3)	11.0% (9.3-12.6)	12.5% (9.8-15.2)
	Mean LOS	3.37 days (3.18-3.55)	3.45 days (3.25-3.66)	3.87 days (3.25-4.21)
	Mean Costs	\$7299 (6597 – 8001)	\$6890 (6334-7646)	\$7345 (6371-8319)
≤ 7 days	In-Hospital Mortality	0.21% (0.17-0.25)	0.18% (0.07-0.28)	0.17% (0.00-0.35)
	ICU Admission	13.6% (11.6-15.5)	11.0% (9.3-12.8)	12.9% (10.3-15.5)
	Mean LOS	3.38 days (3.19-3.57)	3.51 days (3.32-3.74)	4.18 days (3.79-4.57)
	Mean Costs	\$7331 (6612-8050)	\$7138 (6470-7807)	\$8037 (6879-9195)
≤ 14 days	In-Hospital Mortality	0.21% (0.17-0.26)	0.17% (0.08-0.25)	0.15% (0.03-0.27)
	ICU Admission	13.6% (11.6-15.5)	11.1% (9.4-12.7%)	13.2% (10.6-15.8)

	Mean LOS	3.36 (3.17-3.55)	3.50 (3.30-3.71)	4.23 (3.85-4.61)
	Mean Costs	\$7301 (6592-8009)	\$7089 (6441-7737)	7790 (6770-8811)
≤ 30 days	In-Hospital Mortality	0.23% (0.18-0.27)	0.14% (0.07-0.21)	0.17% (0.09-0.26)
	ICU Admission	13.6% (11.6-15.5)	11.5% (9.8-13.3)	13.5% (11.0-16.1%)
	Mean LOS	3.35 (3.16-3.54)	3.49 (3.26-3.72)	4.13 (3.82-4.44)
	Mean Costs	\$7283 (6573-7993)	\$7000 (6364-7635)	\$7782 (6822-8742)

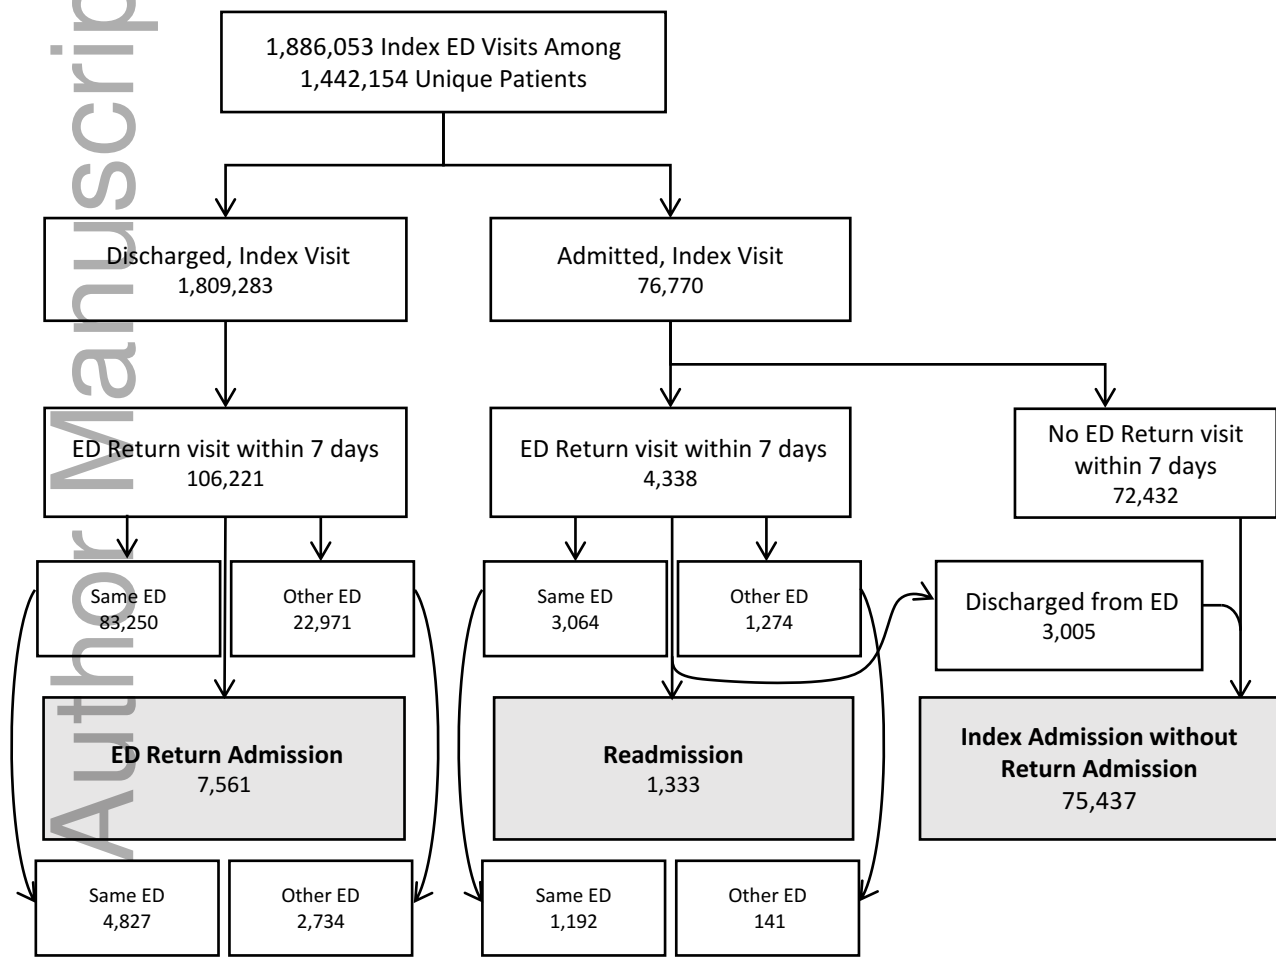

*All models adjusted for age, sex, race, Feudtner comorbidities, primary payer.

Figure Legends

Figure 1. Identification of Return Visit Cohorts

Derivation of the three study cohorts is shown, including the two exposure subgroups—ED Return Admission and Readmission—and the control group--Index Admission without Return Admission.
