Experimental Procedures

General Considerations. All air- and moisture-sensitive manipulations were performed using standard Schlenk techniques or in an inert atmosphere drybox with an atmosphere of purified nitrogen. The drybox was equipped with a cold well designed for freezing samples in liquid nitrogen as well as a -35 °C freezer for cooling samples and crystallizations. Solvents were purified using a Glass Contour solvent purification system through percolation through a Cu catalyst, molecular sieves, and alumina. Solvents were then stored over sodium and/or sieves. Benzene- d_6 and chloroform- d were purchased from Cambridge Isotope Laboratories. Benzene- d_6 was dried with molecular sieves and sodium, and degassed by three freeze–pump–thaw cycles. Chloroform- d was distilled from CaH_2 .

Metal halides, NaH, 9-borabicyclo[3.3.1]nonane, potassium bis(trimethylsilylamide), $NaNO_2$, KOAc, and KEt_3BH , $TBANO_2$, $TBANO_3$, TBAF were purchased from commercial vendors and used as received. Anhydrous hydrazine was purchased from Sigma Aldrich, degassed, and passed through activated alumina prior to use. $^1HNN^{tBu}$ and ($^{allyl}NN^{tBu}$) were synthesized according to literature procedures.^{1,2}

NMR spectra were recorded on Varian Vnmrs 700, Varian MR400, or Bruker Advance Neo 500 spectrometers. 1H , ^{13}C , and ^{11}B chemical shifts are reported in parts per million (ppm) relative to

tetramethylsilane and referenced internally to the residual solvent peak. ^{11}B spectra were referenced on a unified scale, where the single primary reference is the frequency of the residual solvent peak in the ^1H NMR spectrum. ^{11}B spectra are referenced vs. $\text{BF}_3(\text{OEt}_2)$. Multiplicities are reported as follows: singlet (s), doublet (d), triplet (t), quartet (q), pentet (p), multiplet (m). When reported, purity of diamagnetic species was assessed using quantitative NMR with hexamethyldisiloxane (HMDSO) as an internal standard. Infrared spectra were recorded using a Nicolet iS10 FT-IR spectrometer equipped with Smart Diamond Attenuated Total Reflectance (ATR) sampling accessory. Samples were either diluted into dry KBr and recorded as pellets or collected using ATR sampling accessory. MALDI-TOF data were collected on a Bruker AutoFlex Speed with samples prepared under inert atmosphere in an anthracene matrix.

Samples for elemental analysis were crystallized from slow diffusion of pentane into concentrated THF solutions. After isolation of crystalline material, each sample was dried in vacuo for 5 hours before transfer to a glass ampoule fitted with a sealable adapter. The samples were transferred from the glovebox and attached to the Schlenk line. While under vacuum, each sample was flame sealed to ensure a rigorously moisture and air free transit. The samples were shipped to Atlantic Microlabs for analysis. Despite moisture/air free shipping conditions, the samples were analyzed under ambient conditions. For complexes 2, $2\text{-N}_2\text{H}_4$, and $(^{\text{ene}}\text{NN}^{\text{tBu}})\text{FeBr}_2$, the carbon content was anomalously high. The Fe/second-sphere borane complexes readily undergo hydrolysis, and we note that incorporation of hydrates significantly improves the elemental analysis data. For transparency, we report the elemental analysis data with *and* without hydrates.

Single crystals of $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}$, $[(^{\text{BBN}})_2\text{NN}^{\text{tBu}}(\text{OAc})](\text{K-18-crown-6})$, $[(^{\text{BBN}})_2\text{NN}^{\text{tBu}}(\text{NO}_2)](\text{K-18-crown-6})$, $[(^{\text{BBN}})_2\text{NN}^{\text{tBu}}(\text{H})]\text{K}$, $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{FeCl}_2$, $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{NiBr}_2$, $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{ZnCl}_2$, $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{NiBr}_2(\text{N}_2\text{H}_4)$, $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{ZnCl}_2(\text{N}_2\text{H}_4)$, $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{ZnBr}(\text{N}_2\text{H}_3)$, $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{ZnCl}(\text{N}_2\text{H}_3)$, and $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{FeBr}(\text{N}_2\text{H}_2)$ were mounted on a Rigaku AFC10K Saturn 944+ CCD-based X-ray diffractometer equipped with Micromax-007HF Cu-target microfocus rotating anode ($\lambda = 1.54187 \text{ \AA}$) operated at 1.2 kW power (40 kV, 30 mA). The X-ray intensities were measured at 293 K with the detector placed at a distance 42.00 mm from the crystal. Rigaku d*trek images were exported to CrysAlisPro³ and CrystalClear Expert 2.0 r16⁴ for processing and corrected for absorption.

Single crystals of $(^{\text{ene}}\text{NN}^{\text{tBu}})\text{FeBr}_2$, $(^{\text{propargyl}}\text{NN}^{\text{tBu}})\text{FeBr}_2$, $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{FeBr}_2$, and $(^{\text{BBN}})_2\text{NN}^{\text{tBu}}\text{FeBr}_2(\text{N}_2\text{H}_4)$ suitable for X-ray diffraction were coated with poly(isobutylene) oil and quickly transferred to the goniometer head of a Bruker AXS D8 Quest diffractometer with a fixed chi angle, a sealed tube fine focus X-ray tube, single crystal curved graphite incident beam monochromator and a Photon100 CMOS area detector. Examination and data collection were performed with Mo $\text{K}\alpha$ radiation ($\lambda = 0.71073 \text{ \AA}$). For all samples, data were collected, reflections were indexed and processed, and the files scaled and corrected for absorption using APEX3.⁵ For all samples, the space groups were assigned and the structures were solved by direct methods using XPREP within the SHELXTL suite of programs⁶ and refined by full matrix least squares against F^2 with all reflections using Shelxl2017 or Shelxl2018⁷ using the graphical interface Shelxle.⁸ If not specified otherwise, H atoms attached to carbon atoms were positioned geometrically and constrained to ride on their parent atoms, with carbon hydrogen bond distances of 0.95 Å for and aromatic C-H, 1.00, 0.99 and 0.98 Å for aliphatic C-H, CH_2 , and CH_3 moieties, respectively. Methyl H atoms were allowed to rotate but not to tip to best fit the experimental electron density. $U_{\text{iso}}(\text{H})$ values were set to a multiple of $U_{\text{eq}}(\text{C})$ with 1.5 for CH_3 , and 1.2 for CH_2 ,

and C-H units, respectively. Additional data collection and refinement details, including description of disorder (where present) can be found with the individual structure descriptions, below.

Synthesis of propargylNN^tBu ligand. Inside of a glovebox, a 200 mL Schlenk flask was charged with sodium hydride (0.565 g, 23.541 mmol), 50 mL THF, and a stirbar. The flask was removed from the glovebox, attached to a Schlenk line, and cooled to -78 °C with a dry ice/acetone bath. Against a flow of N₂, 2-(5-tert-butyl)-1H-pyrazol-3-yl)-6-methylpyridine (3.876 g, 18.003 mmol) was added as a solid. The cold bath was removed and the solution was allowed to gradually warm to room temperature with stirring. Caution! Vigorous H₂ evolution occurs near 0 °C. When H₂ evolution had ceased, propargyl bromide (8.600 g, 72.293 mmol) was added via syringe. The flask was fitted with a reflux condenser and refluxed for 18 hr. The solution was cooled to room temperature and volatiles were removed in vacuo to afford a brown sludge. The material was extracted with 150 mL CHCl₃, filtered over Celite, and dried to afford yellow-brown oil. The crude material was purified by column chromatography (silica, R_f = 0.51 in 2:1 hexane:ethyl acetate) to afford light yellow solid (2.385 g, 9.414 mmol, 52%) assigned as 2-(5-tert-butyl)-1-ethynyl-1H-pyrazol-3-yl)-6-methylpyridine. The product was stored at -35 °C between use and was found to degrade to a brown tar if stored at room temperature. Synthesis of $(^{(BBN)2}NN^{tBu})ZnBr(N_2H_3)$ (5-Br). A 20 mL scintillation vial was charged with **4-Br- N_2H_4** (28.7 mg, 0.038 mmol) and 5 mL of THF. A separate scintillation vial was charged with potassium bis(trimethylsilylamide) (7.6 mg, 0.038 mmol) and 3 mL of THF. Both solutions were frozen, and upon thawing, the KHMDS solution was added dropwise to the stirring solution of **4-Br- N_2H_4** . The solution gradually warmed to room temperature and stirred for 15 minutes before filtration through Celite. Volatiles were removed in vacuo to afford a light yellow powder which was rinsed with 3 x 5 mL pentane. The yellow powder was redissolved in 2 mL ether and filtered through Celite. Volatiles again removed in vacuo to afford a light yellow powder assigned as $(^{(BBN)2}NN^{tBu})ZnBr(N_2H_3)$ (18.7 mg, 73%, purity = 98%). Synthesis of $(^{(BBN)2}NN^{tBu})FeBr(N_2H_2)$ (6). A 20 mL scintillation vial was charged with **2- N_2H_4** (62.4 mg, 0.084 mmol) and 5 mL of THF. A separate scintillation vial was charged with potassium bis(trimethylsilylamide) (16.7 mg, 0.084 mmol) and 3 mL of THF. Both solutions were frozen, and upon thawing, the KHMDS solution was added dropwise to the stirring solution of **2- N_2H_4** . The solution gradually warmed to room temperature and stirred for 15 minutes before filtration through Celite. Volatiles were removed in vacuo to afford a yellow powder which was rinsed with 3 x 5 mL pentane. The yellow powder was redissolved in 5 mL ether and filtered through Celite. Volatiles again removed in vacuo to afford a light yellow powder assigned as $(^{(BBN)2}NN^{tBu})FeBr(N_2H_2)$ (38.8

mg, 68%). Single, X-ray quality crystals were obtained from slow diffusion of pentane into a THF solution at -35 °C. MALDI-TOF of $C_{32}H_{49}B_2BrFeN_3$ ($(^{i}BBN)_2NN^{i}Bu$) $FeBr(N_2H_2) - N_2H_3$: Calc. 633.253; Found 633.074. 1H NMR (THF, 25 °C, 400 MHz) δ = -30.31, -16.89, -15.47, -11.27, -8.79, -6.88, -2.73, 1.07, 1.42, 1.79, 3.59, 3.66, 4.07, 5.02, 5.62, 7.16, 8.54, 9.06, 9.87, 14.27, 15.06, 16.94, 24.06, 39.91, 41.28, 50.27, 55.95. Hydride competition experiment. A 20 mL scintillation vial was charged with **1** (11.1 mg, 0.022 mmol), **1-mono** (8.4 mg, 0.022 mmol) and 3 mL of THF and frozen. Upon thawing, KEt_3BH (22.3 μL , 1M THF solution, 0.022 mmol) was added to the stirring solution. The solution gradually warmed to room temperature and stirred for 15 minutes. The sample was concentrated to 1 mL in vacuo for 1H NMR spectroscopy analysis.

Hydride transfer experiment. A 20 mL scintillation vial was charged with **1-mono** (12.1 mg, 0.032 mmol) and 3 mL of THF and frozen. Upon thawing, KEt_3BH (32.2 μL , 1M THF solution, 0.032 mmol) was added to the stirring solution. The solution gradually warmed to room temperature and stirred for 15 minutes. Volatiles were removed in vacuo to afford a white powder which was rinsed with 3 x 5 mL of pentane. The white solid was redissolved in 1 mL of THF, and to this stirring solution was added **1** (16.0 mg, 0.032 mmol) as a solution in 1 mL of THF. The reaction stirred for 30 minutes at room temperature before an aliquot was taken for 1H NMR spectroscopy analysis.

Nitrite competition experiment. A 20 mL scintillation vial was charged with **1** (13.4 mg, 0.027 mmol), **1-mono** (10.1 mg, 0.027 mmol) and 3 mL of THF. To this stirring solution was added $NaNO_2$ (1.9 mg, 0.027 mmol) and 18-crown-6 (7.1 mg, 0.027 mmol) both as solids. The solution stirred at room temperature for 2 hours, upon which there was a color change from colorless to yellow. The solution was concentrated to 1 mL in vacuo for 1H NMR spectroscopy analysis.

Hydrazine competition experiments. A 20 mL scintillation vial was charged with **1** (10.5 mg, 0.021 mmol), **1-mono** (7.9 mg, 0.021 mmol) and 1 mL of THF. 20 μL of HMDSO were added as an internal standard. To this stirring solution was added N_2H_4 (66.3 μL , 0.159M THF solution, 0.01 mmol) and the reaction stirred for 15 minutes at room temperature. The sample was transferred to a J-Young tube for 1H NMR spectroscopy analysis. The J-Young tube was returned to the glovebox, and 0.5 equiv. of N_2H_4 (66.3 μL , 0.159M THF solution, 0.01 mmol) was added directly to the J-Young tube.

The same procedure was followed for hydrazine competition experiments with **4** and **4-mono**.

Selective nitrite capture experiments

- 1) A 20 mL scintillation vial was charged with **1** (11.7 mg, 0.024 mmol) and 1 mL of THF. A separate scintillation vial was charged with TBAF (6.2 mg, 0.024 mmol) and 1 mL of THF. The TBAF solution was added dropwise to the stirring solution of **1**, and the resulting solution stirred at room temperature for 2 hours before removal of the solvent in vacuo to afford a white solid. The solid was washed with 2 x 5 mL of pentane and redissolved in 0.500 mL of THF for NMR spectroscopy analysis.
- 2) A 20 mL scintillation vial was charged with **1** (13.4 mg, 0.027 mmol) and 1 mL of THF. A separate scintillation vial was charged with $TBANO_2$ (7.8 mg, 0.027 mmol) and 1 mL of THF. The $TBANO_2$ solution was added dropwise to the stirring solution of **1**, resulting in an immediate color change to yellow. The resulting solution stirred at room temperature

for 2 hours before removal of the solvent in vacuo to afford a yellow solid. The solid was washed with 2 x 5 mL of pentane and redissolved in 0.500 mL of THF for NMR spectroscopy analysis.

- 3) A 20 mL scintillation vial was charged with **1** (16.0 mg, 0.032 mmol) and 1 mL of THF. A separate scintillation vial was charged with TBANO₂ (9.3 mg, 0.032 mmol), TBAF (8.4 mg, 0.032 mmol) and 1 mL of THF. The TBANO₂/TBAF solution was added dropwise to the stirring solution of **1**, resulting in an immediate color change to yellow. The resulting solution stirred at room temperature for 2 hours before removal of the solvent in vacuo to afford a yellow solid. The solid was washed with 2 x 5 mL of pentane and redissolved in 0.500 mL of THF for NMR spectroscopy analysis.
- 4) A 20 mL scintillation vial was charged with **1** (7.6 mg, 0.015 mmol) and 1 mL of THF. A separate scintillation vial was charged with TBANO₂ (4.4 mg, 0.015 mmol), TBAF (39.9 mg, 0.15 mmol) and 2 mL of THF. The TBANO₂/TBAF solution was added dropwise to the stirring solution of **1**, resulting in an immediate color change to yellow. The resulting solution stirred at room temperature for 2 hours before removal of the solvent in vacuo to afford a yellow solid. The solid was washed with 2 x 5 mL of pentane and redissolved in 0.500 mL of THF for NMR spectroscopy analysis.
- 5) A 20 mL scintillation vial was charged with **1** (9.0 mg, 0.018 mmol) and 1 mL of THF. A separate scintillation vial was charged with TBANO₂ (5.2 mg, 0.018 mmol), TBAF (94.0 mg, 0.360 mmol), TBANO₃ (109.1 mg, 0.360 mmol) and 2 mL of THF. The TBANO₂/TBANO₃/TBAF solution was added dropwise to the stirring solution of **1**, resulting in an immediate color change to yellow. The resulting solution stirred at room temperature for 2 hours before removal of the solvent in vacuo to afford a yellow solid. The solid was washed with 2 x 5 mL of pentane and redissolved in 0.500 mL of THF for NMR spectroscopy analysis.

For the above selective nitrite capture experiments, a THF solution of the anion mixture (containing 20 equiv. F⁻, 20 equiv. NO₃⁻, 1 equiv. NO₂⁻ for Trial 5) was added to **1** in THF evaluate the anion selectivity of the ditopic receptor independent of kinetic factors such as solubility or order of addition.

Hydroboration of propargylNN^tBu. To assess the effect of solvent and temperature on single vs. double hydroboration, we reacted propargylNN^tBu with 2 equiv. 9-BBN in THF. A 20 mL scintillation vial was charged with propargylNN^tBu (33.4 mg, 0.12 mmol) and 3 mL of THF. To this stirring solution was added 9-BBN (30.3 mg, 0.25 mmol) dissolved in 1 mL of THF. The solution stirred at room temperature for 12 hours. The THF solvent was concentrated in vacuo, and a ¹H NMR spectrum was collected on the light-yellow solution. The ¹H NMR spectrum showed partial conversion (~67% as judged by pyz-CH) to the ditopic ligand **1**. The ¹H NMR spectrum also showed olefinic resonances, indicating that the other species (~33%) corresponds to the monoborylated “ene” ligand. This data clearly indicates that double hydroboration with 9-BBN is accessible at room temperature in THF solvent. Therefore, the selectivity observed for the generation of Fe and Zn “ene” complexes using the same reaction conditions is unique to coordinated (propargyl)NN^tBu.

Hydroboration of (propargylNN^tBu)ZnBr₂. To assess the generality of post-metalation hydroboration only hydroborating a single time, we targeted synthesis of (propargylNN^tBu)ZnBr₂ followed by hydroboration. A 20 mL scintillation vial was charged with propargylNN^tBu (220.0 mg, 0.82 mmol) and 3 mL of THF. A separate scintillation vial was charged with ZnBr₂ (184.0 mg, 0.82 mmol) and 2 mL of THF. To the stirring ZnBr₂ slurry was added propargylNN^tBu dropwise, and the

solution stirred at room temperature for 16 hours before the THF solvent was removed in vacuo to afford a white solid. The white solid was rinsed with 3 x 5 mL of pentane and assayed for purity by ^1H NMR spectroscopy. A 20 mL scintillation vial was then charged with (*propargyl*NN^{tBu})ZnBr₂ (50.2 mg, 0.10 mmol), 9-BBN (31.0 mg, 0.25 mmol), and 5 mL of THF. The solution stirred at room temperature for 16 hours before the THF solvent was removed in vacuo to afford an off-white solid. The solid was rinsed with 2 x 3 mL of pentane and 2 x 3 mL of ether to afford a white solid assigned as (*ene*NN^{tBu})ZnBr₂. The ^1H NMR spectrum of the product exhibited clear olefinic resonances, indicating *single* hydroboration instead of double hydroboration.

Hydrolysis of 1. A J-Young tube was charged with **1** (25.2 mg, 0.05 mmol) and 600 μL of THF. To this J-Young tube was added H₂O (101 μL of 0.2 M solution in THF, 0.10 mmol) and the sample was monitored by ^1H NMR spectroscopy. After 10 minutes, a new species is evident in the ^1H NMR spectrum. After 1 hour, **1** was completely converted into a new species.

Synthesis of 1-D. A scintillation vial was charged with **1** (21.3 mg, 0.04 mmol), NaBD₄ (5.4 mg, 0.13 mmol) and 3 mL of THF. This slurry stirred at room temperature for 16 hours before the solution was filtered through filter paper. The THF solvent was removed in vacuo to afford a white solid, which was rinsed with 3 x 3 mL of pentane. ^1H NMR and IR spectroscopy data were collected on the isolated solid.

Determination of Acceptor Numbers

Acceptor numbers were determined by the Gutmann-Beckett method⁹ via the equation:

$$\text{acceptor number} = 2.21 \times (\bar{\delta}_{\text{sample}} - 41.0)$$

where $\bar{\delta}_{\text{sample}}$ is the experimentally determined chemical shift in the ^{31}P NMR.

For each determination, 0.250 mL of a triethylphosphine oxide stock solution (0.1242 M, THF) were combined with an equimolar amount of substrate (either **1** or **1-mono**) in 0.500 mL THF and stirred at room temperature for 10 minutes before transfer of the solution to a J-Young tube. A sealed triethylphosphine oxide capillary was added and the ^{31}P NMR spectra were referenced to this internal standard (+43.36 ppm). The ^{31}P resonances are reported relative to phosphoric acid.

Computational Details

DFT calculations were performed using the Gaussian 09 revD01 software package¹⁰ using the B3LYP functional¹¹ and an ultrafine integration grid for all atoms. All reported compounds underwent geometry optimization with the 6-31G(d,p) basis set,¹² followed by vibrational frequency calculations. These were used to verify that the structures were truly local energetic minima by the absence of imaginary vibrational modes and to provide entropies of formation at 25 °C. Energies were determined by applying the free energy and enthalpy corrections from the frequency calculations to the scf energies from single point calculations of the optimized geometries using the higher-level 6-311G(d,p)¹³ basis set for all atoms. For determination of Brønsted acidity, an acetonitrile solvation model was used with the same 6-311G(2d,p) basis set

for all atoms except Zn, which was treated with 6-311G(2d).¹⁴ The calculated pKa values were calibrated to those of pyridine/pyridinium.¹⁵

To evaluate the extent to which functional choice changed thermodynamic values, we calculated ΔG values for hydride, fluoride, nitrite, and acetate addition to both **1** and **1-mono**. The optimized structures using B3LYP-D3BJ/6-31G(d,p) were used as the input geometries for single point calculations. We examined the single point energies using the functionals wb97xd, PBE1PBE, and bp86 all with the 6-311G(d,p) triple zeta basis set. Across all functionals, there is no significant change in the thermodynamic trends. The data is summarized below.

Refinement details:

One of the dangling side ligands was refined as disordered over two orientations by an approximate 2-fold rotation around the CH₂-CH₂ bond. The disorder extends to the entire side-ligand. The two disordered moieties were restrained to have similar geometries. The U^{ij} components of ADPs for disordered atoms closer to each other than 2.0 Angstrom were restrained to be similar. Subject to these conditions the occupancy ratio refined to 0.660(3) and 0.340(3).

A benzene solvate molecule is disordered around an inversion center. The disorder is partially correlated to the ligand disorder, but exactly 1:1. The benzene ring was constrained to resemble an ideal hexagon (AFIX 66). A rigid bond restraint (RIGU) was applied to its atoms.

Refinement details:

A THF molecule was refined as disordered. The two disordered moieties were restrained to have similar geometries as another not disordered THF molecule. U^{ij} components of ADPs for disordered atoms closer to each other than 2.0 Angstrom were restrained to be similar. Subject to these conditions the occupancy ratio refined to 0.583(8) and 0.425(4).

A pentane molecule was refined as 1:1 disordered across an inversion center. Atom positions were freely refined. U^{ij} components of ADPs for disordered atoms closer to each other than 2.0 Angstrom were restrained to be similar.
