

## II. REDUCED SU(3) MATRIX ELEMENTS \*

D. BRAUNSCHWEIG \*\*

*Dept. of Physics, University of Michigan, Ann Arbor, Michigan 48109, USA*

Received 8 February 1978

### PROGRAM SUMMARY

*Title of program:* REDUCED SU(3) MATRIX ELEMENTS

*Catalogue number:* ABKH

*Program obtainable from:* CPC Program Library, Queen's University of Belfast, N. Ireland (see application form in this issue)

*Computer:* AMDAHL 470V/6, IBM 360/370; *Installation:* Univ. of Michigan, Ann Arbor, Mich.

*Operating system:* MTS

*Program language used:* FORTRAN

*High speed storage required:* 212 kwords

*No. of bits in a word:* 32

*Overlay structure:* none

*No. of magnetic tapes required:* none

*Other peripherals used:* card reader, line printer (card punch)

*No. of cards of combined program and test deck:* 907

*Card punching code:* EBCDIC

*CPC library programs used:*

*Catalogue number:* ABKG

*Title:* REDUCED SU(3) CFPS

*Ref. in CPC:* 14 (1978) 109

*Catalogue number:* AAC\*

*Title:* DATA FOR ABKG

*Ref. in CPC:* 14 (1978) 109

\* Work supported by the U.S. National Science Foundation.

\*\* Present address: Goddard Space Flight Center, Seabrook, MD, USA.

**Keywords:** Nuclear physics, SU(3), SU(4), shell model, matrix elements, nuclear structure, pseudo-SU(3), one-body operators, two-body operators, theoretical methods

#### *Nature of physical problem*

Reduced SU(3) matrix elements (RME) are calculated for a general one or two body tensor operator, between arbitrary shell model states in an  $SU(3) \times SU(4)$  or  $SU(3) \times SU(2)$  scheme. Matrix elements in the angular momentum scheme can then be obtained by multiplying these RME with the appropriate  $SU(3) \supset R(3)$  coupling coefficients available through the code of ref. [2].

#### *Method of solution*

One and two body tensor operators are explicitly constructed in terms of fermion creation operators. Since the  $\langle BRA |$  and  $| KET \rangle$  states obtained by using the appropriate routines of the code of ref. [1] are also written in terms of fermion creation operators, the overlap can be calculated directly. This method is typically 2–3 orders of magnitude faster than the usual CFP expansion.

#### *Restrictions on the complexity of the problem*

The  $\langle BRA |$  and  $| KET \rangle$  states are restricted to those that can be calculated with the code of ref. [1]. No other restrictions exist.

#### *Typical running time*

It is a critical function of the nuclear shell, the number of particles as well as the options selected.

#### *Unusual features of the program*

The same array naming convention adopted in the code of ref. [1] is kept. This allows a saving of up to 35% of high speed storage in IBM 360/370 or similar operating systems.

## LONG WRITE-UP

### 1. Introduction

Conventional computer codes [3] for shell model calculations are limited to the  $j-j$  coupling scheme, and even though these can handle matrices of very large size the types of problems which can be tackled are very limited. To date detailed calculations [4] have been carried out only for many nucleon systems in the  $p_{1/2}p_{3/2}$  and  $s_{1/2}d_{3/2}d_{5/2}$  (or  $p_{1/2}p_{3/2}f_{5/2}$ ) shells with no excitations out of the “valence” shell.

Often an underlying symmetry can be used to reduce the size of the shell model matrix. For some nuclei SU(3) symmetry [5] (or pseudo SU(3) symmetry) [6] may make a severe truncation of the shell model matrix physically meaningful. In a nucleus of good SU(3) symmetry the low-lying nuclear states may be approximated very well in terms of a small number (typically 3–6) of irreducible representations of SU(3). In such a nucleus therefore a shell model calculation in the SU(3) scheme may be characterized by a small basis.

The main difficulty in performing SU(3) shell model calculations is then concentrated in the calculation of matrix elements of one and two body operators in this basis.

We describe below a FORTRAN program which calculates reduced matrix elements (RME) *directly*, that is, without using the usual coefficient of fractional parentage (CFP) expansion (see eqs. (16) and (17) of ref. [7]). This results in a speed increase of 2–3 orders of magnitude.

The full matrix element can then be obtained by multiplying the RME by the appropriate  $SU(3) \supset R(3)$  and  $R(3) \supset R(2)$  Wigner coefficients available through the code of ref. [2].

Although the present program is restricted to the calculation of RME for many-particle shell model states with particles of the same shell only; the combination of the codes for RME’s of one-body operators with the CFP code of ref. [1] and straightforward recoupling techniques make it possible to calculate matrix elements which involve

particle-hole excitations. However, the CFP expansion needed for this purpose is simple, since a two-body operator can involve at most 2-particle excitations even if the basis includes complicated core excitations.

The RME program calls several routines from the codes ABKG [1] and ACRM [2] henceforth called CFP PROGRAM and SU(3) PACKAGE respectively. Familiarity with the CFP PROGRAM is assumed. Care has been exercised to maintain the naming and dimensioning conventions adopted for the CFP PROGRAM. Generality is preserved as well, in that the RME program allows calculations to be performed in:

- 1) Any major oscillator shell.
- 2) Both neutron-proton formalism (NPF) or full spin-isospin formalism (FSIF) are acceptable.
- 3) Optimization available for the prolate or oblate limit is obtained by calculating the RME from the highest weight state or lowest weight state, respectively.
- 4) No SU(4) coupling coefficients are needed since both  $\langle \text{BRA} |$  and  $| \text{KET} \rangle$  states can be lowered in SU(4) according to the needs of a particular user.
- 5) Arbitrary one and two body tensor operators of good SU(3) symmetry in either the NPF or FSIF are acceptable.

## 2. Method of calculation

Throughout this section we will use the notation introduced in ref. [1]; furthermore we will illustrate our method using the full spin-isospin formalism.

The calculation of the RME proceeds in the following order:

- 1) Explicit construction of the many-particle states in terms of fermion creation operators.
- 2) Explicit construction of the desired tensor operators in terms of fermion creation and destruction operators.
- 3) The tensor operators constructed in 2) are allowed the act on the  $| \text{KET} \rangle$  states and the result is overlapped with the  $\langle \text{BRA} |$  states.
- 4) Finally the  $SU(3) \supset SU(2) \times U(1)$  and  $SU(2) \supset U(1)$  dependence is factored out from the overlap by using the appropriate Wigner coefficients.

### 2.1. Construction of the many-particle states

The many-particle states are classified according to the IR of  $SU(3) \times SU(4)$ . The subgroup chains used are  $SU(3) \supset SU(2) \times U(1)$  and  $SU(4) \supset [SU(2) \times SU(2)]$ . Since the many-particle states are highest weight in  $SU(3)$  and  $[SU(2) \times SU(2)]$  they can be denoted by:

$$|n(\lambda\mu) \alpha(PP'P'') \beta ST\rangle, \quad (1)$$

where  $n$  = number of particles,

- $(\lambda\mu)$  =  $SU(3)$  irreducible representation,
- $\alpha$  = inner multiplicity label for  $SU(3)$  needed to distinguish multiple occurrence of  $(\lambda\mu)$  in a given space symmetry;  $\alpha = 1, 2, \dots, \alpha_{\max}$ ,
- $(PP'P'')$  = supermultiplet labels,
- $S$  = spin,
- $T$  = isospin,
- $\beta$  = inner multiplicity label for  $SU(4)$  needed to distinguish multiple occurrences of  $ST$  in a given supermultiplet;  $\beta = 1, 2, \dots, \beta_{\max}$ .

The method used to construct these many-particle states is spelled out in detail in sections 2.1 through 2.4 of ref. [1]. The highest weight states of (1) can be expressed in terms of fermion creation operators as:

$$|n(\lambda\mu) \alpha(PP'P'') \beta ST\rangle = \sum_{i_1 < i_2 < \dots < i_m} Z_{i_1 i_2 \dots i_m}^{(\lambda\mu)\alpha(PP'P'')\beta ST} a_{i_1}^+ a_{i_2}^+ \dots a_{i_m}^+ |0\rangle, \quad (2)$$

where  $i_j$  is an index which labels the single-particle levels (see fig. 1 of ref. [1]).

The single-particle fermion creation operator have tensorial character given by:

$$a_{(\eta_0)\epsilon\Lambda M_\Lambda \frac{1}{2}M_S \frac{1}{2}M_T}^+ = T^{(\eta_0)\epsilon\Lambda \frac{1}{2}\frac{1}{2}}_{M_\Lambda M_S M_T}, \quad (3a)$$

where  $\eta$  is the number of oscillator quanta in the shell under consideration; similarly the tensorial character of the single-particle destruction operators is given by:

$$a_{(\eta_0)\epsilon\Lambda M_\Lambda \frac{1}{2}M_S \frac{1}{2}M_T}^- = (-)^{\eta + \Lambda - M_\Lambda + \frac{1}{2} - M_S + \frac{1}{2} - M_T} T^{(\eta_0)\epsilon\Lambda \frac{1}{2}\frac{1}{2}}_{-M_\Lambda - M_S - M_T}. \quad (3b)$$

## 2.2. Construction of one and two body tensor operators

In this section we illustrate the construction of two body tensor operators. One body operators are obtained in a similar fashion.

We denote a two particle creation operator by:

$$[a^+ a^+]^{(\lambda\mu)\epsilon\Lambda M_\Lambda S M_S T M_T}, \quad (4)$$

where

$(\lambda\mu)$  = SU(3) IR,

$\epsilon\Lambda M_\Lambda$  = subgroup labels of SU(3) belonging to  $SU(2) \times U(1)$ ,

$S$  = spin,

$M_S$  = Z-projection of  $S$ ,

$T$  = isospin,

$M_T$  = Z-projection of  $T$ .

The square brackets [...] denote SU(3) as well as spin and isospin coupling. Then the two body operator of arbitrary tensorial character can be expressed as:

$$\begin{aligned} & [[a^+ a^+]^{(\lambda_1\mu_1)S_1T_1} [a a]^{(\mu_2\lambda_2)S_2T_2}]^{(\lambda\mu)\rho_{12}\epsilon\Lambda M_\Lambda S M_S T M_T} = \sum_{\substack{\epsilon_1 \Lambda_1 \Lambda_2 \\ M_{\Lambda_1} M_{S_1} M_{T_1}}} (-)^{\frac{1}{3}(\mu_2 - \lambda_2) + \frac{1}{6}\epsilon_2 - M_{\Lambda_2} + S_2 - M_{S_2} + T_2 - M_{T_2}} \\ & \langle (\lambda_1\mu_1) \epsilon_1 \Lambda_1; (\mu_2\lambda_2) \epsilon_2 \Lambda_2 | (\lambda\mu) \epsilon\Lambda \rangle_{\rho_{12}} \langle \Lambda_1 M_{\Lambda_1} \Lambda_2 M_{\Lambda_2} | \Lambda M_\Lambda \rangle \langle S_1 M_{S_1} S_2 M_{S_2} | S M_S \rangle \langle T_1 M_{T_1} T_2 M_{T_2} | T M_T \rangle, \\ & [a^+ a^+]^{(\lambda_1\mu_1)\epsilon_1\Lambda_1 M_{\Lambda_1} S_1 M_{S_1} T_1 M_{T_1}} [a a]^{(\lambda_2\mu_2) - \epsilon_2 \Lambda_2 - M_{\Lambda_2} S_2 - M_{S_2} T_2 - M_{T_2}} \\ & = \sum_{i_1 < i_2, i_3 < i_4} X_{i_1 i_2 i_3 i_4}^{[(\lambda_1\mu_1)S_1 T_1 (\mu_2\lambda_2)S_2 T_2]^{(\lambda\mu)\rho_{12}\epsilon\Lambda M_\Lambda S M_S T M_T}} a_{i_1}^+ a_{i_2}^+ a_{i_3} a_{i_4}, \end{aligned} \quad (5)$$

where the double barred coefficient is a reduced  $SU(3) \supset SU(2) \times U(1)$  Wigner coefficient and the single barred coefficients are ordinary Clebsh–Gordan coefficients.

$\rho_{12}$  labels multiple occurrence of  $(\lambda\mu)$  in the Kronecker product  $(\lambda_1\mu_1) \times (\mu_2\lambda_2)$ ; this label is not needed for one body operators.

The two particle operators of (2) need not be calculated since they are read in as input data from set A (see section 4.1.1).

## 2.3. Calculation of the overlap

If we let the operator of eq. (5) act on the  $|KET\rangle$  of eq. (1) we get:

$$[[a^+ a^+]^{(\lambda_1\mu_1)S_1T_1} [a a]^{(\mu_2\lambda_2)S_2T_2}]^{(\lambda\mu)\rho_{12}\epsilon\Lambda M_\Lambda S M_S T M_T} |n(\lambda_k\mu_k) \alpha_k(P_k P'_k P''_k) \beta_k S_k T_k\rangle$$

$$= \sum_{j=2,m} \sum_{\substack{i_1 < i_2 \\ i_1 < i_2 \\ i_3 < i_4}} \sum_{i'_1 < \dots i'_{j-1} < i'_{j+1} \dots i'_{l-1} i'_{l+1} \dots i'_m} X_{i_1 i_2 i_3 i_4}^{[(\lambda_1\mu_1)S_1 T_1 (\mu_2\lambda_2)S_2 T_2]^{(\lambda\mu)\rho_{12}\epsilon\Lambda M_\Lambda S M_S T M_T}}$$

$$Z_{i_1' i_2' \dots i_m'}^{\alpha_k \mu_k} \alpha_k (P_k P'_k P''_k) \beta_k S_k T_k \delta_{i_3 i_j'} \delta_{i_4 i_l'} a_{i_1'}^+ a_{i_2'}^+ \dots a_{i_{j-1}'}^+ a_{i_1}^+ a_{i_{j+1}}^+ \dots a_{i_{l-1}'}^+ a_{i_2}^+ a_{i_{l+1}}^+ \dots a_{i_m'}^+ |0\rangle . \quad (6)$$

If  $i_1 < i_{j-1}'$  or  $i_1 > i_{j+1}'$  or  $i_2 < i_{l-1}'$  or  $i_2 > i_{l+1}'$  we have to reorder the fermion operators, this introduces a phase factor  $P$ . The final result can then be written as:

$$\sum_{i_1'' < i_2'' < \dots i_m''} X^0 Z^k P^k a_{i_1''}^+ a_{i_2''}^+ \dots a_{i_m''}^+ , \quad (7)$$

where we have replaced the quantum numbers associated with  $X$  by the superscript “0” and the quantum numbers associated with  $Z$  by a superscript “k”.

We can now evaluate the overlap  $O_\Lambda$  as:

$$\begin{aligned} O_\Lambda &= \langle n(\lambda_b \mu_b) \alpha_b (P_b P'_b P''_b) \beta_b S_b T_b | [a^+ a^+]^{(\lambda_1 \mu_1) S_1 T_1} [a a]^{(\mu_2 \lambda_2) S_2 T_2} ]^{(\lambda \mu) \rho_{12} \epsilon \wedge M_\Lambda S^M S^T M T} \\ &\quad | n(\lambda_k \mu_k) \alpha_k (P_k P'_k P''_k) \beta_k S_k T_k \rangle \\ &= \sum_{i_1'' i_m''} Z^b X^0 Z^k P^k \langle 0 | a_{i_m''}^+ \dots a_{i_1''}^+ a_{i_1'}^+ \dots a_{i_m'}^+ | 0 \rangle = \sum_{i_1'' i_m''} Z^b Z^0 Z^k P^k \delta_{i_1'' i_m''} . \end{aligned} \quad (8)$$

Since the  $\langle \text{BRA} |$  and  $| \text{KET} \rangle$  states are highest weight in SU(3), the total number of admissible values of  $\Lambda$  is equal to  $\rho_{\max}$ , the number of times  $(\lambda_b \mu_b)$  is contained in the Kronecker product  $(\lambda_k \mu_k) \times (\lambda \mu)$ .

The RME is then obtained by solving the system of linear equations:

$$\begin{aligned} O_\Lambda &= \sum_{\rho=1}^{\rho_{\max}} \langle (\lambda_k \mu_k) \epsilon_k \Lambda_k; (\lambda \mu) \epsilon \Lambda | (\lambda_b \mu_b) \epsilon_b \Lambda_b \rangle \langle \Lambda_k \Lambda_k \Lambda M_\Lambda | \Lambda_b \Lambda_b \rangle \langle S_k S_k S M_S | S_b S_b \rangle \langle T_k T_k T M_T | T_b T_b \rangle \\ &\quad \langle n(\lambda_b \mu_b) \alpha_b (P_b P'_b P''_b) \beta_b S_b T_b ||| [a^+ a^+]^{(\lambda_1 \mu_1) S_1 T_1} [a a]^{(\lambda_2 \mu_2) S_2 T_2} ]^{(\lambda \mu) \rho_{12} S^T} ||| n(\lambda_k \mu_k) \alpha_k (P_k P'_k P''_k) \beta_k S_k T_k \rangle_\rho , \end{aligned} \quad (9)$$

where

$$\epsilon_k = 2\lambda_k + \mu_k , \quad \Lambda_k = \mu_k/2 , \quad \epsilon_b = 2\lambda_b + \mu_b , \quad \Lambda_b = \mu_b/2 . \quad (10)$$

The triple barred quantity in eq. (9) is the RME.

### 3. Structure of the program

The overall structure of the RME program is illustrated in the block diagram of fig. 1.

Block 1 contains a MAIN routine as well as subroutine RME and subroutine TENSOR. These are the only routines provided as part of the RME program; their function is described in detail in comment statements at the beginning of each routine.

In block 2 the explicit construction of the states of eq. (2) is performed. All the subroutines in block 2 are part of the CFP program; we therefore do not provide them as part of the RME code; they can be obtained from the CPC library (code number ABKG). The subroutines which are enclosed in dotted square in fig. 1 need only be included for calculations in the FSIF.

In block 3 the  $SU(3) \supset SU(2) \times U(1)$  and the  $SU(2) \supset U(1)$  Wigner coefficients are calculated. These are needed for eq. (5) and eq. (9). All the subroutines in block 3 are part of the SU(3) PACKAGE but for convenience they were repeated as part of the deck ABKG and can be obtained from it.

Communication between different blocks is established through labelled COMMON blocks. The meaning of the variables in a given block is explained in comment cards at the beginning of those subroutines which need this common block for communication.

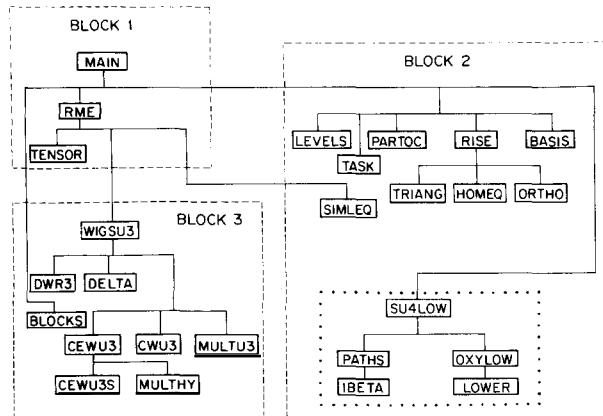

Fig. 1. Flow diagram for program reduced SU(3) matrix elements.

Because of implicit dimensioning in the subroutines of block 3 it is important to have these routines follow those of block 1 and 2 in the source deck.

#### 4. Input/output

Input to the RME program is done exclusively in the MAIN routine. The structure of the input data deck is illustrated in fig. 2. The input data is of two types as we describe below.

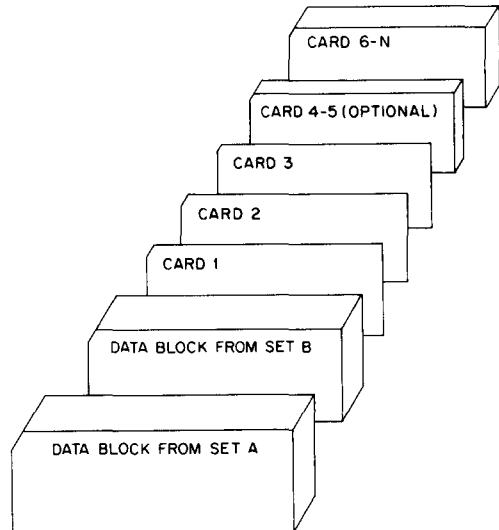

Fig. 2. Structure of the input data deck.

Table 1  
FSIF

Operator	Shell	First card	Last card
1-body	p	1	13
2-body	p	14	74
1-body	sd	151	172
2-body	sd	173	451
1-body	fp	1876	1908
2-body	fp	1909	2881
<hr/>			
NPF			
1-body	p	6045	6056
2-body	p	6057	6081
1-body	sd	6082	6094
2-body	sd	6095	6164
1-body	fp	6165	6186
2-body	fp	6187	6389

#### 4.1. Input of type 1

This type of input allows the user to select a particular use of the RME program. By selecting appropriate data sets of type 1 the user may calculate reduced matrix elements for one or two body operators, in either the p, sd, or fp shells, in the FSIF or NPF [8].

The input of type 1 needed for the RME program is *identical* to the input of type 1 used in the CFP program, and therefore should be obtained from the CPC library as data file AAC\*.

Input of type 1 consists of two blocks of input data, the first block to be selected from set A and the second block from set B.

##### 4.4.1. Data set A

Data blocks of set A contain the necessary information to describe fully the one or two body tensor operators needed.

Since a one (two) body operator is constructed by coupling a one (two) particle creation operator with a one (two) particle destruction operator we can take advantage of the fact that the one (two) particle creation operators are already described by data set A of the CFP program, and we can therefore avoid constructing a new data set A for the RME program.

It should be pointed out that since a general two-body tensor operator may contain both symmetrically and antisymmetrically coupled pairs, both the symmetric and antisymmetric two-particle operators must be read in and stored.

Table 1 gives the first and last card of data file AAC\* which make up data set A for a particular application. The meaning of the quantities in set A is the same as in the CFP program and the reader is referred to ref. [1] for details.

##### 4.1.2. Data set B

Data blocks of set B contain a table for the reduction  $U(n) \supseteq SU(3)$  where  $n = 3$  for the p shell,  $n = 6$  for the sd shell and  $n = 10$  for the fp shell. These tables are needed in the calculation of highest weight states.

Table 2 gives the first and last card of data file AAC\* which make up data set B for a given shell. The meaning of the quantities in set B is the same as in the CFP program, and the reader is referred to ref. [1] for details.

Table 2

Space symmetry U( $n$ )	Restrictions on SU(3) content	First card	Last card
U(3)	none	6390	6399
U(6)	none	6400	6525
U(10)	$\alpha_{\max} \leq 10$	6526	7423

#### 4.2. Input of type 2

This data must be provided by the user.

Cards 1–5 define the  $\langle \text{BRA} |$  and  $| \text{KET} \rangle$  states desired. The meaning of the quantities read in as well as their use is identical with that of ref. [1] except for the following changes:

*Card 1:* IPRST, IPRLVL, IPRTSK, MPUNCH FORMAT (16I4)

the variable MPUNCH was added to control punching or logical I/O unit 7 of the RME.

*Card 2:* IREPMLN, IREPMLX, LOHI FORMAT (16I4)

the variables IREPMLN and IREPMLX are not used.

*Card 3:* ((LINBUF(I,J), I = 1, IMAX), J = 1,2) FORMAT (16I4)

J = 2 is not used since we assume that the set of  $\langle \text{BRA} |$  states is the same as the set of  $| \text{KET} \rangle$  states.

*Cards 4–5:* same as in the CFP program.

*Cards 6–N:* JM1(I), MU1(I), IS1(I), IT1(I), JM2(I), MU2(I), IS2(I), IT2(I), JM3(I), MU3(I), IS3(I), IT3(I)  
referring to eq. (5) the meaning of the quantities in cards 6–N is:

$$\begin{aligned} \text{JM1}(I) &= \lambda_1, & \text{MU1}(I) &= \mu_1, & \text{IS1}(I) &= S_1, & \text{IT1}(I) &= T_1, & \text{JM2}(I) &= \mu_2, & \text{MU2}(I) &= \lambda_2, & \text{IS2}(I) &= S_2, \\ \text{IT2}(I) &= T_2, & \text{JM3}(I) &= \lambda, & \text{MU3}(I) &= \mu, & \text{IS3}(I) &= S, & \text{IT3}(I) &= T, \end{aligned} \quad (11)$$

If the NPF is being used one should set IT1(I) = IT2(I) = IT3(I) = 0.

#### 4.3. Output

The output is controlled by the value of the variables read-in in card 1 as follows:

IPRST = 0: no printing of the many-particle states,

= 1: print the many-particle states.

IPRLVL = 0: no printing of single particle levels ,

= 1: print single particle levels,

= 2: print both the single particle levels and the explicit forms of raising and lowering operators.

IPRTSK = 0: no printing of summary of states,

= 1: print a summary of states to be calculated.

MPUNCH = 0: no punching of the RME,

= 1: punch-out the RME as well as the many-particle states on logical I/O unit 7.

### 5. Program modifications

The size of arrays needed to calculate the  $\langle \text{BRA} |$  and  $| \text{KET} \rangle$  states depend strongly on the nuclear shell under consideration as well as the number of particles involved. Therefore provision is made for easy adjustment of

Table 3

CSECT	Parameter	Oscillator shell		
		p	sd	fp
CTOP	NP21	50	100	200
RME	NS7	66	276	780
	NS8	12	24	40
	NP22	500	1500	3750
	NP23	500	1000	2000

dimensions in accordance with the needs of a particular user.

Instructions for the proper dimensioning of arrays needed in subroutines of blocks 2 and 3 can be found in ref. [1] and ref. [2], respectively.

The procedure for dimensioning the arrays which appear in the subroutines of block 1 is similar to the one adopted in the CFP program. Table 3 gives the suggested value for the parameters which determine the size of arrays in those labelled COMMON blocks which do not appear in the CFP program. In the event that the dimension is insufficient a relevant message will be printed asking the user to increase its value and execution is stopped.

As with the CFP program, considerable saving of high speed storage (up to 35%) can be achieved by using half-length words for all integer arrays which begin with the letter "L". In IBM 360/370 or similar operating systems this can be done by simply inserting as the first statement of each subroutine IMPLICIT INTEGER\*2(L).

## 6. Test run

The RME program has been extensively tested by checking against RME sum rules. We reproduce below a test run, as well as, the necessary input data required.

In this test run we calculate RME in the FSIF for two-body operators in the fp shell.

The set of  $\langle \text{BRA} |$  and  $| \text{KET} \rangle$  states are all the states of the form:

$$|n = 6(\lambda\mu)\alpha(P'P'')\beta S = P T = P'\rangle$$

with  $2\lambda + \mu = 30$  and  $2\lambda + \mu = 27$  the two-body tensor operators are:

$$[[a^+a^+](^{60})^{20}[aa]^{(06)20}]^{(00)00}, [[a^+a^+](^{22})^{20}[aa]^{(22)02}]^{(22)22},$$

$$[[a^+a^+](^{41})^{22}[aa]^{(22)20}]^{(25)42}, [[a^+a^+](^{03})^{22}[aa]^{(14)22}]^{(17)44}.$$

The input deck required for this run is:

DATA SET A:	2-body fp shell	CARDS 1909-2881
