1. INTRODUCTION

This document is a report by The University of Michigan Transportation Research Institute (UMTRI) to the Honda Research and Development Company on the results of the first tire testing program using the HONDA/UMTRI Motorcycle Tire Dynamometer.

Tests were conducted on three individual tires. In this report, these tires are identified as T1, T2, and T3, and are identified in Table 1.1.

Table 1.1. Test Tires.

Tire ID	Tire	
T1	Bridgestone Mag. Mopus - S702	3.60S19
T2	1st Bridgestone Mag. Mopus - L302	4.10S18
T3	2nd Bridgestone Mag. Mopus - L302	4.10S18

As originally planned, only two tires were to be sampled. However, during an early series of high-speed tests, the roadway support bearing of the MTS Flat Trak roadway failed causing the generation of excessive heat. Damage to the bearing, road belt and tire T2 resulted. On the advice of the Honda engineer observing the test, tire T2 was replaced with tire T3 in all subsequent tests.

Tests were conducted to examine both transient and steady-state tire properties. Transient and steady-state properties of tires T1 and T2 were examined in Test 1 - Relaxation Tests. All Relaxation Tests were conducted at low speed (on the order of 1 Km/hr). Each tire was subjected to one condition of load, inflation pressure, and temperature and 25 conditions of combined slip and camber angles. Further steady-state tests (Tests 2 and 3) were conducted on T3. These tests included various conditions of temperature, inflation pressure, and velocity, as well as five slip angle and five camber angle conditions. Further details of test procedures and conditions are given in Section 2.

Data resulting from these tests are presented in several forms. First, complete time histories of each run of Tests 2 and 3 can be found in the two enclosed volumes. (Time histories from Test 1 have previously been presented to Honda.) The larger volume contains graphical presentations of these time histories; the smaller volume contains time histories presented tabularly. These, and the Test 1 time histories, have also been reduced to more readily understandable numerics. The reduced data are presented graphically in Sections 3 and 4, along with explanations of the reduction method. Tabular results of the reduced data are presented in Appendices A, B, and C. (Note that time history data in the attached volumes appear in English units, while the reduced data in this document are in metric units.)

Test procedures and results will be discussed in the following sections of this report. Section 2 will consider test procedures and conditions for both relaxation and steady-state tests. In Section 3, the results of the relaxation test are presented in reduced form. Section 4 presents the reduced data derived from the steady-state tests. Sections 3 and 4 also include a discussion of the data reduction algorithms.

2. TEST PROCEDURES

2.1 Relaxation Test Procedure

The test conditions for Test 1 (Relaxation Tests) are described in Table 2.1. Inflation pressures were continuously controlled by an air regulator throughout the tests. Tire temperatures were uncontrolled, and since velocity was low, were assumed to be room temperature. Test velocities were approximately 1 Km, with an initial transient due to the fact that all tests begin at zero speed. The complete matrix of slip and camber angle conditions shown were run for each tire.

Table 2.1. Test Conditions for the Relaxation Tests.

Tire	Inflation Pressure kg/cm ² (psi)	Temperature °C	Velocity Km/hr	Vertical Load Kg (lb)
T1	1.75 (25)	Room Temp.	≈ 1	120 (265)
T2	2.25 (32)	Room Temp.	≈ 1	160 (353)

For both T1 and T2 the following slip angle/camber angle conditions were tested.

Camber Angle	Slip Angle				
	+1	0	-1	-3	-5
0	X	X	X	X	X
10	X	X	X	X	X
20	X	X	X	X	X
30	X	X	X	X	X
40	X	X	X	X	X

For each test run, with the road belt stationary, the tire was positioned to the proper slip and camber angle while still suspended above the roadway. The tire was then moved downward in the wheel plane until it contacted the road and obtained the specified vertical load. At this time, the roadway belt was accelerated to 1 km/hr.

Initial motion of the roadway was used to trigger the data-taking process. From this starting point, data samples were taken at a rate of 50 samples/sec/channel for a total period of 20 seconds. Typically, this resulted in gathering data over a travel distance of about 5 meters or 2-1/2 tire revolutions. One individual test run of this type was conducted for each slip and camber angle condition.

Results for this series of tests are presented in Section 3.

2.2 Steady-State Tests

The test conditions for the steady-state tests are presented in Table 2.2.

Table 2.2. Steady-State Test Conditions

Tire	Inflation Pressure Kg/cm ² (psi)	Temperature °C	Velocity Km/hr	Vertical Load Kg (1b)
T3	2.25 (32)	25 ± 5°	1,40,80,120	160 (353)
T3	2.41 (34.25)	25 ± 5°	1,40,80,120	160 (353)
T3	2.60 (37)	25 ± 5°	1,40,80,120	160 (353)
T3	2.41 (34.25)	50 ± 5°	1,40,80,120	160 (353)

For each of the above conditions, the following slip angle and camber angle conditions were tested:

Camber Angle	Slip Angle				
	+1	0	-1	-3	-5
0	X	X	X	X	X
10		X			
20			X		
30			X		
40		X			

The nominal inflation pressure for this tire was 2.25 Kg/cm² at room temperature (25°C). The elevated pressures of 2.41 and 2.60 Kg/cm²

were established experimentally. This experiment consisted of inflating the tire to 2.25 Kg/cm² at 25°C and then running the tire at high speed, high load, and in the presence of eight heat lamps (total 2800 KW) to produce elevated running temperatures. Periodically, the tire was stopped and surface temperature and inflation pressure were measured. In this way, a pressure/temperature relationship was established. The two elevated inflation pressures to be used were defined as those which occurred at 50 and 80°C.

It was found that, even with external heating from the lamps, the maximum attainable surface temperature was approximately 65°C. Accordingly, the pressure corresponding to 80°C was obtained by extrapolation.

In performing this experiment, surface temperatures were measured with a non-contacting optical pyrometer and with a contacting thermal-couple pyrometer. At zero velocity (and with heat lamps off), these measurements were found to agree within 1°C. In the first trial of this experiment, inflation pressure was measured with a common tire gauge. However, it was suspected that, due to the large number of measurements taken, a significant drop in inflation pressure occurred due to air loss. Accordingly, a second experiment in which pressure was measured with an electronic transducer permanently installed on the valve stem was conducted. The results of this experiment were used to establish the test inflation pressures.

Thereafter, during actual testing, inflation pressure was continually controlled by an air regulator to the specified test pressure. Tire surface temperature was established within the specified boundaries just prior (approximately 30 seconds) to each run, either by heating or cooling as required. Just after each run (again approximately 30 seconds), tire surface temperature was again measured. Both of these temperature measurements were made with the optical pyrometer with the tire at zero velocity and heat lamps off.

We note that Honda originally requested testing at 80°C and the associated pressure. However, establishing this high temperature level was found to be impossible without extraordinary effort beyond the budget capability of this project.

Tests were made at velocities of 1, 40, 80, and 120 Km/h. Tests at 160 Km/h were originally planned, but were abandoned for two reasons. First, the previously mentioned failure of the roadway support bearing occurred during the first attempt at the 160 Km/h condition. It was considered unreasonable to risk further damage to the roadway by persisting with these high-speed tests. Second, the D.C. drive servo system which controls belt speed malfunctioned several times as 160 Km/h was approached. Until this problem is diagnosed, it seems unreasonable to operate at this velocity.

Two variations of the test procedure were used, depending on test velocity. For tests conducted at 1 Km/h, a test duration on the order of 15 seconds is required to obtain two full tire rotations. In the "normal" dynamic mode, tests are currently limited to 5 seconds due to computer memory limits, but the specially prepared relaxation tests (always static) allow a 20-second test duration. Thus, for 1 Km/h tests, the procedure described for relaxation tests was used.

At higher velocities, tire rotational velocity is sufficiently high to allow testing in the normal test mode of the machine. In this mode, the test procedure is as follows:

- 1) The tire is initially placed on the roadway at a low level of vertical load, zero slip angle, a specified initial camber angle, and a roadway belt velocity of 5 Km/h.
- 2) Belt velocity is increased to the specified test condition.
- 3) On Command, vertical load is increased to the specified test condition.
- 4) On Command, a specified time history of slip angle and camber angle is executed and data is gathered. Data sampling occurs at 250 Hz for a maximum duration of 5 seconds.

With this procedure, more than one slip angle/camber angle can be tested in one run. In this program, the nine specified conditions of slip and camber were accomplished in four runs. The four types of test runs

used have been identified as ASTEP1, ASTEP2, GSTEP1, and GSTEP2. Table 2.3 describes the conditions covered in each of these test types.

Table 2.3. Slip and Camber Angle Conditions
of the Four Test Types

<u>Test Name</u>	<u>Alpha</u>	<u>Gamma</u>
ASTEP1	1	0
	0	0
	-1	0
ASTEP2	-3	0
	-5	0
GSTEP1	0	10
	0	20
GSTEP2	0	30
	0	40

Table 2.4 indicates the chronological test sequence. The table also shows that one particular test, viz., ASTEP1 at 25°C, 2.25 Kg/cm², and 40 Km/h, was repeated periodically throughout the program. The purpose of including these runs was to attempt to track the influence of wear on the test tire properties, particularly since the test matrix was quite asymmetric in slip and camber angles.

Figure 2.1 shows the data derived from the repeat tests. It should be noted that the dynamometer was damaged during test 85 so that this data is somewhat suspect. Damage occurred in a manner which seriously degraded the measurement of the vertical position (rolling radius) of the tire. Since this measurement has a strong influence in the calculation of M_x , the results for M_x from test 85 were clearly in error and are, therefore, not included.

Table 2.4. Test Sequence

Temperature °C	Pressure Kg/cm ²	Velocity(s) Km/h	Number of Tests
25	2.25	40	1 (ASTEP1)
25	2.25	40-120	11*

3. TEST 1 RESULTS

Processing of the low-speed, relaxation tests ($V \approx 1 \text{ Km/h}$) of tires T1 and T2 includes the calculation of the steady-state values and an estimation of the relaxation lengths. The following function was used to curve fit the data (FY, MX, and MZ).

$$F(X) = SS - X(1)e^{-X/L}$$

where

SS = steady-state value

X = distance

X(1) = first curve fit parameter = SS-F(0) where
F(0) is the zero time data point

L = second curve fit parameter = relaxation length

The steady-state values were computed by averaging the data over the last revolution of the tire (each test is approximately 2.5 to 3 revolutions). These values were then used by the following algorithm to estimate the relaxation lengths.

1. Print all steady-state values

2. Estimate X(1) and L from the data

$$X(1) = SS - F(0)$$

$$L = X' \text{ where } F(X') = SS - X(1)e^{-1}$$

3. Print L and F(X') for each variable

4. Use the results of (2) as first guesses for the minimization iteration

5. Attempt to minimize the sum of the squares

$SUMSQ = \sum (SS - X(1)e^{-X/L} - F(X))^2$ over fifteen
equally spaced points of the first 1 to 1.5 feet
of data

6. Print results - $X(1)$, L , SUMSQ, distance points (X),
data points ($F(X)$), and calculated curve points
($SS = X(1)e^{-X/L}$)

Appendix A contains the output of the above algorithm for tires T1 and T2. In a few cases, the data were either not close to being exponential or the noise due to tire nonuniformities eclipsed any exponential trend. This caused the program to terminate prematurely (i.e., no results were printed).

The steady-state values are summarized in Tables 3.1 and 3.2 and in Figures 3.1 and 3.2. The relaxation length estimates (missing values are set to zero) and a curve fit index ($SUMSQ/SS^2$) are listed in Table 3.3. The relaxation lengths with respect to F_y are reviewed in Figure 3.3. Clear trends with respect to slip and camber angles are apparent from the figure. Examination of the time histories reveals that the most erroneous data points of the figure result from the fact that the time histories involved are not truly of the assumed, exponential form. In general, the curve fit index data points in Appendix A and time history plots should be used to evaluate the quality of these estimates.

Table 3.3. Relaxation Lengths Summaries

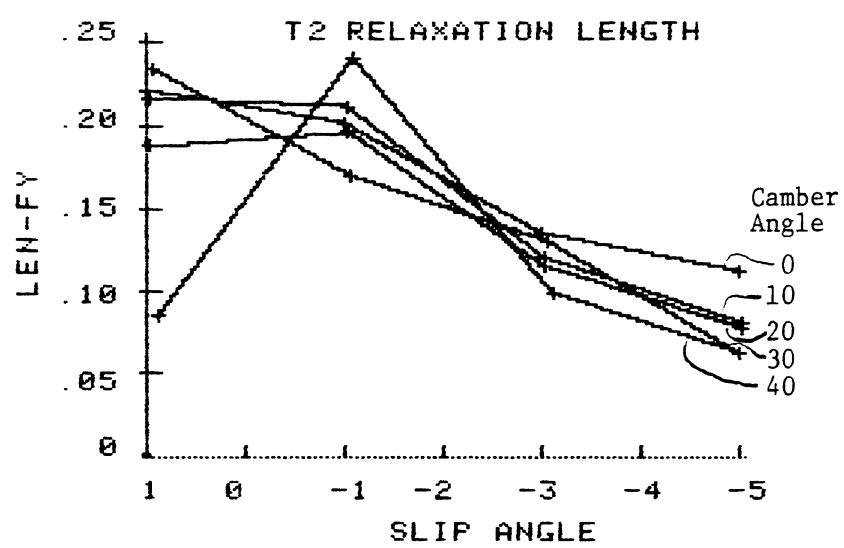

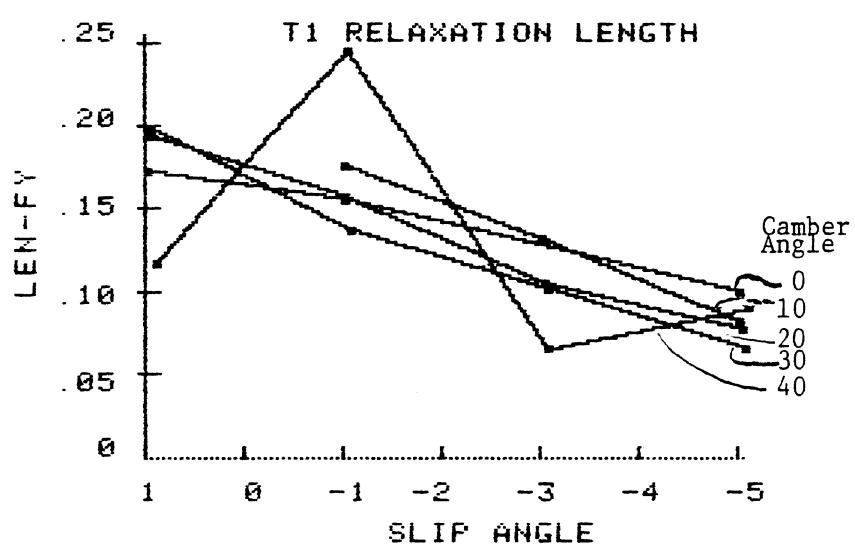

Figure 3.3. Lateral force relaxation lengths.

4. TESTS 2 AND 3 RESULTS

Processing of the speed tests ($V=40-120$ Km/h) of tire T3 involved calculating the steady-state values of forces, moments, and geometry for each test condition. Since these tests are a combination of two or three test conditions, all tests are divided into data processing segments. Figure 4.1 depicts the alpha time history for the test ASTEP1. Steady-state values of all variables of interest were calculated for each segment. The following algorithm was used to generate these values.

1. Calculate the average rotational velocity for the segment (i.e., WAV in rad/sec)
2. Calculate the average time for a revolution of the tire ($TREV = 2\pi/WAV$)
3. Calculate the maximum number of full revolutions (NMAX) in .8 seconds
4. Average all forces, moments, and geometric variables over $NMAX*TREV$ seconds
5. Print all steady-state values

Appendix B contains the output generated by the processing of the speed tests ($V=40$ to 120 Km/h) of tire T3. Test information and the steady-state results for each segment are listed.

The algorithm discussed in Section 3 was used to generate the steady-state values of the low-speed ($V \leq 1$ km/h) tests of tire T3. Appendix C contains the results of this processing.

These listings were then used to generate the summary tables and plots which follow (Tables 4.1 to 4.5 and Figures 4.2 to 4.18).

APPENDIX B

PROCESSING RESULTS OF TESTS 2 AND 3 FOR TIRE T3

All comments indicate:

1. Beginning and ending tire temperature in °C (e.g.,
 $T = 23, 24$)
2. Nominal Test Velocity (e.g., $V = 40$)

Results Printed

SEG - Test Segment Number

REVS - Number of Tire Revolutions

TSTRT - Beginning Time for Averaging

TEND - Ending Time for Averaging

VELOCITY - SS Belt Velocity in mph

ALPHA - SS Slip Angle in degs

GAMMA - SS Inclination Angle in degs

RHO - SS Path Curvature 1/ft

FX - SS Rolling Resistance in lbs

FY - SS Lateral Force in lbs

FZ - SS Vertical Load in lbs

MX - SS Overturning Moment in in-lbs

MY - SS Rolling Resistance Moment in in-lbs

MZ - SS Aligning Moment in in-lbs

OMEGA - Average Rotational Velocity in rad/sec

APPENDIX C

PROCESSING RESULTS OF STATIC TESTS OF TIRE T3

No Curve Fit was Done for These Tests

Steady-State Values Printed

ALPHA - SS Slip Angle in degs

GAMMA - SS Inclination Angle in degs

FX - SS Rolling Resistance in lbs

FY - SS Lateral Force in lbs

FZ - SS Vertical Load in lbs

MX - SS Overturning Moment in in-lbs

MY - SS Rolling Resistance Moment in in-lbs

MZ - SS Aligning Moment in in-lbs
