## "SALTING-OUT" CHROMATOGRAPHY: EMPIRICAL EQUATIONS RELATING $R_F$ VALUES TO ATOMIC REFRACTION CONSTANTS\*

MERLE MASON AND LAWRENCE C. WEGIENKA

*Department of Biological Chemistry, University of Michigan, Ann Arbor, Mich. (U.S.A.)*

Investigations by TISELIUS<sup>1</sup> have shown that dyestuffs and some proteins show a very marked increase of adsorption onto filter paper and silica gel in the presence of salts in large concentrations. The underlying principle, called 'salting-out' adsorption<sup>2</sup>, has since been applied in a number of instances in chromatographic procedures for proteins<sup>3</sup> and in a few instances in the chromatography of smaller compounds<sup>4,5</sup>. In the present study of paper chromatography based on the salting-out principle, compounds of various types were chromatographed using saturated ammonium sulfate as the developing solvent. This report lists the  $R_F$  values and presents equations relating them to atomic refraction constants.

\* Supported in part by a grant (Project R no. 340) from the Horace H. Rackham School of Graduate Studies, University of Michigan.

TABLE I  
 COMPARISON OF EXPERIMENTAL AND CALCULATED  $R_F$  VALUES

Experimental  $R_F$  values are the average of 6 to 8 determinations. The average deviation for each compound was 0.02–0.03  $R_F$  units. Calculated  $R_F$  values were determined from equations in the text.  $\Delta$  is defined as 100 (Exptl.  $R_F$ —Calc.  $R_F$ ).

Compound	$MR_D$	Exptl. $R_F \times$ 100	Calc. $R_F \times$ 100	$\Delta$	Compound	$MR_D$	Exptl. $R_F \times$ 100	Calc. $R_F \times$ 100	$\Delta$
L-Phenylalanyl-L-phenylalanine	86.8	17	15	+2	3-Hydroxy-L-kynurenine	55.7	27	30	—3
Glycylglycine	29.1	87	90	—3	3,5-Diiodo-L-tyrosine	72.4	7	5	+2
Glycyl-DL-alanine	33.8	87	88	—1	$\alpha$ -Aminoisobutyric acid	25.8	80	85	—5
Glycyl-L-leucine	47.6	69	71	—2	L-Methionine	38.4	74	72	+2
Glycylglycylglycine	41.8	90	91	—1	L-Ethionine	43.0	63	62	+1
DL-Alanylglycine	33.8	88	86	+2	L-Cysteine	28.8	86	88	—2
DL-Alanylglycylglycine	46.4	88	88	0	L-Cystine	56.3	86	85	+1
DL-Leucylglycine	47.6	70	71	—1	L-Homocystine	65.5	69	68	+1
DL-Leucylglycylglycine	60.2	71	69	+2	S-Phenyl-L-cysteine	53.2	37	36	+1

\* 20 was subtracted from the  $MR_D$  values for each imidazol or guanidine group in the compound; 15 was subtracted for each pyridine nucleus.

## EXPERIMENTAL

26 peptides, 32  $\alpha$ -amino acids and 30 miscellaneous organic compounds were chromatographed at room temperature ( $24^\circ\text{C} \pm 2^\circ$ ) by the ascending method on Whatman No. 1 filter paper using as the developing solvent saturated aqueous solutions of ammonium sulfate.

Aliphatic amines were detected on the paper by spraying with 0.1% ninhydrin solution in water-saturated *n*-butanol followed by heating for 5 to 10 minutes at  $100^\circ\text{C}$ . Longer heating resulted in a pink coloration of the paper, due probably to reaction of ninhydrin with ammonium sulfate. To detect  $\alpha$ -keto acids, the sheets were sprayed with 0.05% *o*-phenylenediamine dihydrochloride in 10% trichloroacetic acid solution and after heating at  $100^\circ\text{C}$  for 2 minutes were inspected for fluorescence under ultraviolet light<sup>6</sup>. All of the other compounds tested were detected either by their fluorescence or by their absorption of ultraviolet light.

## RESULTS

HAGDAHL AND TISELIUS<sup>2</sup> noted in paper chromatograms of 7 amino acids and 6 peptides developed with concentrated phosphate buffer solutions that the  $R_F$  values were *inversely* proportional to the molecular weights in contrast to the generally direct relationship obtained using organic solvents. Such an inverse relationship is apparent also in the  $R_F$  values obtained in the present study using saturated ammonium sulfate solutions (Table I). A more precise relationship was achieved in the present study, however, by relating the  $R_F$  values to molecular refraction ( $MR_D$ ) values as indicated in Equations 1, 2 and 3. Equation 1 is applicable to the peptides, Equation 2, to the amino acids containing one or two sulfur atoms per molecule, and Equation 3, to the other amino acids and miscellaneous compounds.

$$\log (1/R_F - 1) = -0.61 + 0.030 (MR_D - 15A - 10B - 5C) \quad (1)$$

$$\log (1/R_F - 1) = -1.02 + 0.045 (MR_D - 15A - 10B - 5C) \quad (2)$$

$$\log (1/R_F - 1) = -0.80 + 0.045 (MR_D - 15A - 10B - 5C) \quad (3)$$

The three equations were derived from Figs. 1 and 2, which, in turn, were based on the data in Table I. In each equation,  $A$  represents the number of aliphatic amino and

Figs. 1 and 2. Relationship of  $R_F$  values to structural characteristics of the solutes.  $A$ ,  $B$ ,  $C$  and  $MR_D$  are defined in the text. Crosses in Fig. 2 represent sulfur-containing amino acids; all other compounds are represented by circles.

amide (including peptide) groups,  $B$ , the number of carboxyl groups and  $C$ , the number of hydroxyl groups.  $MR_D$  values were obtained by adding atomic refraction constants<sup>7</sup>. Additional constants were assumed for pyridine, guanidine and imidazol groups as indicated in Table I. Since few representatives of each of these types were available for testing, the latter constants must be regarded as tentative.

$R_F$  values calculated by the use of Equations 1, 2 and 3 are presented in Table I for comparison with the experimental values. Good agreement (deviations of 0.05  $R_F$  units or less) was found for 85 of the 88 compounds tested. Therefore, the equations appear to be valid for the types of compounds studied.

#### DISCUSSION

Use of pre-determined group-constants as illustrated above permits the prediction of  $R_F$  values of compounds of known structure. Conversely, experimental  $R_F$  values can provide information concerning the structures of unknown substances of the general types of those listed in Table I even without preliminary isolation and purification.

MARTIN *et al.*<sup>8,9</sup> derived a theory of partition chromatography according to which the  $R_F$  value of a substance is related to its partition coefficient,  $\alpha$ , in the two phases of the solvent system and to the ratio of the volume of the organic phase ( $A_1$ ) to the volume of the aqueous phase ( $A_2$ ) as shown in Equation 4.

$$\alpha = A_1/A_2 (1/R_F - 1) \quad (4)$$

Difficulties in evaluating  $\alpha$  as well as  $A_1/A_2$  have undoubtedly limited the use of this equation. Such difficulties are avoided to a large extent in Equations 1, 2 and 3, since the  $R_F$  values are related in these equations to published atomic constants<sup>7</sup> and readily determined group constants.

The term,  $\log (1/R_F - 1)$ , appearing in Equations 1, 2 and 3 was suggested by consideration of MARTIN's<sup>8,9</sup> treatment of partition chromatography. Why this term should also appear in equations concerning salting-out chromatography or why molecular refraction is a decisive factor is not at present apparent to us.

#### SUMMARY

Peptides,  $\alpha$ -amino acids and miscellaneous organic compounds were chromatographed on filter paper using saturated ammonium sulfate solution as the developing solvent. Equations relating  $R_F$  values to molecular refraction constants were derived empirically. Applications of such equations in predicting  $R_F$  values and obtaining information concerning molecular structure are discussed briefly.
