(Received 18 October 1967)

Abstract—Analytical expressions for total radiances and equivalent widths of isolated spectral lines with combined Doppler and collision broadened profiles are presented for isothermal paths.

WHEN a spectral line is broadened by contributions from both the Doppler effect and Lorentz collision damping, the absorption coefficient, k , at frequency ν can be expressed by:⁽¹⁾

$$k(\nu, a) = k_0 \frac{a}{\pi} \int_{-\infty}^{\infty} \frac{e^{-y^2}}{a^2 + (\omega - y)^2} dy \quad (1)$$

where $k_0 = (\ln 2)^{1/2} S / \gamma_D$, $a = (\ln 2)^{1/2} (\gamma_L / \gamma_D)$, $\omega = (\ln 2)^{1/2} (\nu - \nu_0) / \gamma_D$, S is the line strength, γ_L is the Lorentz half-width at half-maximum intensity, γ_D is the Doppler half-width at half-maximum intensity, and ν_0 is the line center frequency. The absorption coefficient [equation (1)] is not a simple function compared to those for Lorentz and Doppler lines which lead to explicit expressions for the equivalent widths† in terms of known functions:^(2,3)

$$W_L = 2\pi\gamma_L f(x_L) \quad (2)$$

where $x_L = SX / (2\pi\gamma_L)$, X is the optical depth, and $f(x_L) = x_L e^{-x_L} [I_0(x_L) + I_1(x_L)]$;

$$W_D = (\pi / \ln 2)^{1/2} \gamma_D g(x_D) \quad (3)$$

where

$$x_D = (\ln 2 / \pi)^{1/2} SX / \gamma_D \quad \text{and} \quad g(x_D) = \sum_{n=0}^{\infty} \frac{(-1)^n x_D^{n+1}}{(n+1)!(n+1)^{1/2}}$$

The subscripts L and D refer to Lorentz and Doppler, respectively. The subscript V will refer to lines with combined Doppler and collision broadened profiles, which are referred to as Voigt lines since the subject was originally discussed by VOIGT.⁽¹⁾ For isothermal

† Equivalent width, W , is defined as: $W \equiv \int_0^{\infty} \alpha(\nu) d\nu$, where $\alpha(\nu)$ is the absorbance.

lines, the total radiance $N = N_{\nu_0}^*(T)W$, where $N_{\nu_0}^*(T)$ is the Planck function of temperature T and line center frequency ν_0 , and the Planck function is assumed to be invariant over the spectral interval occupied by a single line, so the analysis can be made in terms of W only.

Curves of growth for Voigt lines, i.e. plots of $\log_{10}\{N_{\nu}/[2\gamma_D N_{\nu_0}^*/(\ln 2)^{1/2}]\}$ versus $\log_{10}(10.6x_D)$, for various values of a have been obtained by VAN DER HELD⁽⁴⁾ and PENNER and KAVANAGH.⁽⁵⁾ The ordinate can also be expressed as $\log_{10}\{W_{\nu}/[2\gamma_D/(\ln 2)^{1/2}]\}$. Equations (2) and (3) can be expressed in terms of a and x_D and in forms which can readily be compared with the curves of growth:

$$W'_L = W_L/[2\gamma_D/(\ln 2)^{1/2}] = \pi a f\{x_D/[2\sqrt{(\pi)a}]\} \quad (4)$$

$$W'_D = W_D/[2\gamma_D/(\ln 2)^{1/2}] = [\sqrt{(\pi)/2}]g(x_D). \quad (5)$$

Similarly, we define

$$W'_V = W_V/[2\gamma_D/(\ln 2)^{1/2}]. \quad (6)$$

Figures 1-7 are plots of equations (4) and (5) on the Voigt curves of growth^(4,5) for $a = 5 \times 10^{-4}$, 5×10^{-3} , 5×10^{-2} , 5×10^{-1} , 1, 2, and 10. These figures, plots of $\log_{10}W'_L$, $\log_{10}W'_D$, $\log_{10}W'_V$ against $\log_{10}(10.6x_D)$, show that W'_V can be represented by W'_D at some distance below the intersection point $(x_{D,I})$ of the W'_D and W'_L curves and by W'_L at some distance above $x_{D,I}$. For $a > 0.2$ there is no intersection point but a merging of the two curves into one; in this case the Lorentz and Voigt curves are identical over the entire range of optical depths.

When the Lorentz and Doppler curves do intersect, in the region about $x_{D,I}$, W'_V is slightly higher than either W'_L or W'_D . Note that the smaller the value of a , the larger the value of $x_{D,I}$. For example, for $a = 5 \times 10^{-4}$, $x_{D,I} \sim 10^4$ and for $a = 5 \times 10^{-2}$, $x_{D,I} \sim 5 \times 10^2$.

Above $x_{D,I}$ the curve for W'_V can be approximated by:

$$W'_V = W'_L \left[1 + \frac{3}{8} \frac{\pi^{1/2}}{ax_D} + \frac{45}{128} \frac{\pi}{(ax_D)^2} + \frac{6615}{3072} \frac{\pi^{3/2}}{(ax_D)^3} \right]. \quad (7)$$

Equation (7) was obtained by using an approximate expression⁽⁶⁾ for $k(\nu, a)$, valid for $a < 0.1$, and applying the conditions valid for strong lines. It is similar to an expression obtained by PLASS and FIVEL.⁽⁷⁾ For $x_D \gg x_{D,I}$, $ax_D \gg 1$, and $\{\frac{3}{8}[\sqrt{(\pi)/ax_D}]\} \ll 1$ so that equation (7) reduces to $W'_V = W'_L$. Below $x_{D,I}$ an empirical fit to W'_V was made:

$$W'_V = W'_D \left(1 + \frac{\sqrt{ax_D}}{2\pi^{n/2}} \right) \quad (8)$$

where n is specified by the order of magnitude of a : $a \sim 10^{-n+1}$. For example, for $a = 5 \times 10^{-4} \sim 10^{-3}$, $n = 4$. For $x_D \ll x_{D,I}$, $(\sqrt{ax_D}/2\pi^{n/2}) \ll 1$ so that equation (8) reduces to $W'_V = W'_D$.

Comparisons of values obtained with equations (7) and (8) and those obtained by VAN DER HELD⁽⁴⁾ and read from the curves of PENNER and KAVANAGH⁽⁵⁾ are given in Table 1. Equations (7) and (8) yield values which agree fairly well with those of van der Held. For $a = 5 \times 10^{-1}$ the values obtained with equation (4) were consistently smaller than those of van der Held. Except for one point, values of W'_V obtained with equation (4) agreed with values read off the graph⁽⁵⁾ to within 10 per cent.

A more detailed presentation of these results is given in Ref. 8.
