SYNTHESIS AND CHARACTERIZATION OF SOME CIS COMPLEXES
OF THE TYPE [Cr(pn)₂AX]ⁿ⁺

(Received 1 November 1971)

Recently we reported the synthesis of the trans-dibromobis-
(propylenediamine)chromium(III) cation (1). Other trans complexes of this type which are known are the difluoro (2) and
dichloro (3). In the case of the corresponding cis complexes
only the difluoro (4) has been fully characterized in the solid state.

In the course of our studies of the acid and base hydroly-
sis of the trans dibromo complex, it became necessary to in-
dependently synthesize the cis bromoaquo species as a possible reaction intermediate. The search for a synthetic route to
this cation has also led to the successful synthesis and charac-
terization of cis-[Cr(pn)₂Cl₂]Cl and cis-[Cr(pn)₂Br₂]Br in the solid state. The large solubilities of these salts preclude
their isolation from aqueous solution as solid samples of rea-
sonable purity. We have developed procedures which overcame
these difficulties.

Experimental

cis-[Cr(pn)₂Cl₂]Cl. The violet chlorodimethylsulfoxide-
chromium(III) complex was prepared according to the method of

*Abbreviations used: en = ethylenediamine, pn = propylene-
diamine = 1,2-diaminopropane.
Pedersen (5) and used as the starting material. Chromium(III) chloride hexahydrate (40 g, 0.15 mole) was dissolved in 80 ml of dimethyl sulfoxide and heated to ~188° to remove the water. The solution was allowed to cool to 110° and stirred while dry propylenediamine (0.30 mole) was added dropwise. The reaction mixture was then heated in an oil bath at 150° for 1 hr and allowed to cool to room temperature. Crystallization of the resulting viscous oil was induced by grinding with fresh acetone. The filtered product was washed with acetone, ether and dried under vacuum at 60° for 1 hr (yield 50 g).

The product was purified by adding 12 g of the crude material to a stirred solution containing 200 ml of absolute ethanol and 100 ml of acetone, filtering and discarding the undissolved material. Treatment of the filtrate with excess absolute ether resulted in a purple precipitate which was removed by filtration, washed with absolute ether and dried under vacuum at 60° for 1 hr. This total yield (8.1 g) was dissolved in 100 ml of boiling propanol, allowed to cool to room temperature, filtered and the resulting crystals discarded. The filtrate was maintained at -18° for 3 hr, filtered and the crystals washed with acetone and absolute ether. The pure violet product is very hygroscopic and was analyzed after drying at 110° to constant weight (yield 1.2 g, 11.1%). Anal. Calcd for [Cr(pn)₂Cl₂]Cl: C, 23.49; N, 18.27; H, 6.58; Cl, 34.75. Found: C, 23.29; N, 18.10; H, 6.64; Cl, 34.57.

This complex was prepared from the above cis-[Cr(pn)₂Cl₂]Cl in a manner similar to that used for
the ethylenediamine analog (6). The cis dichloro complex (1.2 g) was dissolved in 5 ml of H₂O and maintained at 60° for 20 min. Then 4 ml of 48% HBr was added and the solution evaporated on a steam bath under a stream of N₂. This was followed by another 4-ml addition of HBr and the evaporation repeated as before. The moist product was dried by heating at 70° under vacuum and washed with absolute ether. The crude product was then stirred with 130 ml of acetone in the dark for 10 min, filtered, the residue discarded and the product precipitated from the filtrate with excess absolute ether. After drying under vacuum at 60° for 1 hr, the precipitate was treated with 100 ml of boiling nitromethane, the residue discarded and the filtrate kept overnight at -18°. The resulting dark violet crystals were washed with ether and dried under vacuum at 100° for 2 hrs (yield 0.20 g, 12%). Anal. Calcd for [Cr(pn)₂Br₂]Br: C, 16.38; N, 12.73; H, 4.58; Br, 54.48; Cr, 11.82. Found: C, 16.48; N, 12.65; H, 4.51; Br, 54.41; Cr, 11.61.

cis-[Cr(pn)₂(OH₂)Br]²⁺. This cationic species was prepared in solution by dissolving 55 mg of cis-[Cr(pn)₂Br₂]Br in 50 ml of 0.1 N HClO₄ and allowing the complex to aquate for 16 min at room temperature in the dark. The solution was then absorbed on a 40 mm x 9 mm diameter jacketed column of Dowex AG50W-X8 cation exchange resin (100-200 mesh in the H⁺ form). The column was kept at 0° and protected from light with Al foil throughout the elution procedure. The unreacted cis dibromo was eluted with 1 N HClO₄. Additional 1 N HClO₄ was used to slowly move the desired cis bromoaquo band to the bottom of the
column. It was then eluted with 50 ml of 2.0 N HClO₄, and the spectrum recorded. The Cr/Br atom ratio of this species is 1.01 and its elution behavior is very similar to its en analog.

Bromide was determined in the above complexes by potentiometric titration (1) and chromium was measured spectrophotometrically as CrO₄²⁻ after oxidation with alkaline peroxide (3). The dichloro complex was not analyzed for chromium because accurate weighings were precluded due to the hygroscopic nature of this salt. The remaining elements were determined by microanalysis.* The visible absorption spectra of the solid samples in 0.1 N HClO₄ or HNO₃ at 0° were recorded immediately after dissolution with a Cary Model 14 spectrophotometer.

**Discussion**

Some time ago Wendlandt and Sveum (7) described the preparation of cis complexes of the type [Cr(pn)₂X₂]X by a thermal matrix method. This preparative procedure involves heating [Cr(pn)₃]X₃ and an excess of the corresponding ammonium halide at 160° and 210° (for X = Cl and Br respectively). These authors reportedly removed all impurities from the products by vacuum sublimation and characterized their products by elemental analysis and reflectance spectra. Numerous efforts to prepare analytically pure cis dibromo in our laboratory by this method always met with failure. In our hands unreacted tris complex and other impurities were always present at the end of the reported reaction and sublimation times. We found that treatment

of the crude product with absolute alcohol, followed by ether precipitation of the filtrate and repeated recrystallization of the residue with nitromethane gave a material in small yield (<1%) whose %Cr was within the expected range. We abandoned this synthetic route when it was recently demonstrated that the isomeric purity of some thermal matrix products of this type is questionable (5).

Esparza and Garner (8) attempted to prepare pure cis-[Cr(pn)2Cl2]ClO4 in a manner similar to that used for the corresponding en analog but found two major disadvantages in their procedure. First, the product appeared always to contain several per cent pn·2HClO4. Secondly, the reaction mixture proved to be potentially hazardous and on one occasion detonated violently, seriously injuring one of the authors. Our non-aqueous procedure overcomes both of these problems.

We were able to confirm the configurations of the complexes reported here by their spectra and cation exchange characteristics. Table I shows no tetragonal splitting of the low energy bands of these cis complexes which is typical of the trans complexes of this type. The molar absorbancy indices of the cis dichloro complex are ~5% lower than those previously reported (5). Since the elution behavior from H+ Dowex AG50W-X8 resin is known for both trans dihalo species (1,9), it was possible to check for isomeric purity of our cis dihalo products by ion exchange. No discernable trans dihalo contamination was found for either of these cis products by this technique.
