INTRODUCTION

A development problem associated with the Titan II missile was a self-exited longitudinal vibration set up in the missile structure and the rocket engine propellant feed system. At one condition of operation a structure resonance developed which was reinforced by propellant system resonances. The motion of the feed tank and pump caused the outflow to the thrust chamber and the resultant thrust, to vary periodically at the natural frequency of the structural assembly.

This analysis deals primarily with the transients in all the pipes of the engine feed system and especially focuses on the method of representing the turbopump transient characteristics analytically, including the effect of pump inlet impeller cavitation. The quasi-linear partial differential equations of continuity and momentum were solved by the methods of characteristics and the method of specified time intervals, and by use of finite difference methods placed in convenient form for use with a large digital computer. Non-linear friction losses in piping were included, and the turbopump transient pressure rise is included as a non-linear function of the transient flow rate and inlet pump static pressure.

The propellant system analyzed is a full-scale ground test simulation of the missile propellant system. These results were compared with the actual ground tests which included the turbopumps and feed system. In these tests (and in the analytical representation) the engine feed system was hydraulically the same as the
actual missile system except that the engine fuel and oxidizer injectors were simulated by orifices and the engine thrust chamber and nozzle were simulated by a cavitating venturi. The fuel and oxidizer systems were tested separately.
THE ROCKET ENGINE PROPELLANT SYSTEM

A sketch of the rocket engine propellant system is shown in Figure 1. Both the fuel and oxidizer systems include a propellant tank, a line from the tank to the turbopump inlet, the turbopump and a line from the turbopump discharge to the thrust chamber injector. Valves are located upstream of each pump and injector.

A sketch of the oxidizer system ground test configuration which simulates the missile system is shown in Figure 2. The fuel system test simulation was similar. The hydraulic dynamic resistance for the cavitating venturi is twice that of the hydraulic dynamic resistance for the engine nozzle. This fact was taken into account when the test data were evaluated for the missile application, but is of no concern to this treatment since the analysis is of the test configuration.

The fuel and oxidizer turbopump characteristic curves are shown in Figure 3. Since this is a dynamic problem, interest is primarily in the slope of these curves at a particular operating point, such as shown on the curves. The use of these curves as well as other parameters such as friction factors and pressure wave velocities, orifice and venturi coefficients are discussed subsequently.

The fuel and oxidizer used in the test were the same as the missile propellants which are Aerogine 50 (50% Hydrazine, 50% UDMH) and nitrogen tetroxide.

Figure 3. Oxidizer Pump Steady State Characteristics.
FLUID TRANSIENT EQUATIONS

The methods of calculating head and velocity of small time intervals for equally-spaced sections along a pipeline, with inclusion of friction, have been previously reported. The important working equations are briefly summarized:

For the interior sections along a pipe

\[ V_p = \frac{1}{2} \left[ V_R + V_S + g(H_R - H_S)/a_C - (fV^2_C) \Delta t/D \right] \]  \hspace{1cm} (1)

and

\[ H_p = \frac{1}{2} \left[ H_R + H_S + a_C (V_R - V_S)/g \right] \]  \hspace{1cm} (2)

in which \( V_p \) and \( H_p \) are velocity and elevation of a hydraulic grade-line at section \( P \). With reference to Figure 4, it is considered that \( V \) and \( H \) at \( A, C, \) and \( B \) have previously been calculated. \( V_R, V_S, H_R, \) and \( H_S \) are obtained by linear interpolation between \( A, C, \) and \( B \) by the formulas

\[ V_R = V_C + \Theta (V + a)_C (V_A - V_C) \]  \hspace{1cm} (3)

\[ H_R = H_C + \Theta (V + a)_C (H_A - H_C) \]  \hspace{1cm} (4)

\[ V_S = V_C + \Theta (V - a)_C (V_C - V_B) \]  \hspace{1cm} (5)

\[ H_S = H_C + \Theta (V - a)_C (H_C - H_B) \]  \hspace{1cm} (6)

in which \( \Theta = \Delta t/\Delta x \), the preselected mesh ratio for the calculations. \( C^+ \) and \( C^- \) of Figure 4 are the characteristics. For the method to be stable, it is essential that

-7-
Figure 4. Characteristic Curves.
\[ \theta < \frac{1}{|V| + a} \] (7)

in which 'a' is the speed of a pressure pulse wave.

\[ a = \left( \frac{K}{\rho \left(1 + \frac{KD}{E_b}\right)} \right)^{1/2} \] (8)

K is the bulk modulus of elasticity of the fluid, \( \rho \) the mass density, \( E \) the Young's modulus for pipe wall material, \( D \) the pipe diameter, and \( b \) the wall thickness. In the equations, \( g \) is the acceleration of gravity, \( f \) the Darcy-Weisbach friction factor, and \( \Delta t \) the time increment used in the calculations. The subscript \( C \) denotes evaluation of the quantity at the section under consideration for the preceding time increment.

At the end sections of a pipe, the characteristic equations yield one equation in the two unknowns \( V_p \) and \( H_p \). For the downstream end

\[ V_p = V_R - g(H_p - H_C)/a - \frac{1}{2} \Delta t(fV_C^2)/D \] (8)

and for the upstream end

\[ V_p = V_S + g(H_p - H_S)/a - \frac{1}{2} \Delta t(fV_C^2)/D \] (9)

External conditions (pipe end boundary conditions) must supply the extra relationship so that \( V_p \) and \( H_p \) may be calculated.
PIPE END BOUNDARY EQUATIONS

The pipe external or end boundary equations will be given for the oxidizer system pipes. The boundary equations for the fuel system pipes are derived in a similar manner.

As shown in Figure 2 the oxidizer system test configuration was represented by 7 pipes; 1 pipe for the tank, 3 pipes for the pump feed line, 1 pipe to represent the pump, 1 pipe for the pump discharge line and 1 pipe to represent the pulser. Each pipe was divided into sections as previously explained. The boundary equations for the end of each pipe in the system are as follows:

1. **Upstream End of Pipe 1**

   The pressure head at the inlet to pipe 1 is

   \[ H_p(1,1) = H_g \]  

   \[ (10) \]

   where \( H_g \) is the gas pressure head in the tank and \( H_p(1,1) \) is the pressure head in pipe 1 of section 1.

2. **Junction of Pipe 1 and Pipe 2**

   The pressure head at the downstream end of pipe 1 (tank outlet) is equal to the pressure head at the upstream end of pipe 2, so that

   \[ H_p(1,N1) = H_p(2,1) \]  

   \[ (11) \]

   where \( H_p(1,N1) \) indicates the pressure head in pipe 1, section N (the last section) and \( H_p(2,1) \) indicates the pressure head in pipe 2,
section 1. This notation will be used throughout the text. Another
relation is derived from continuity of flow from pipe 1 to pipe 2 as

$$V_p(1,N1) = \left(\frac{D_2}{D_1}\right)^2 V_p(2,1)$$  \hspace{1cm} (12)

where $D_1$ and $D_2$ are the diameters of pipes 1 and 2 respectively.

The above two equations along with the two boundary characteristic equations previously derived (one for each pipe) give the required four equations to solve for the four unknowns, $H_p(1,N1)$, $V_p(1,N1)$, $H_p(2,1)$, and $V_p(2,1)$.

The boundary equations for pipe junctions 2 to 3, 3 to 4, and 6 to 7 are identical to the equations for junction 1 to 2 except for the subscripts.

3. Junction of Pipes 4, 5, and 6

As in the junction of pipes 1 and 2, the pressure head is equal, so that

$$H_p(5,1) = H_p(4,N4)$$  \hspace{1cm} (13)

$$H_p(6,1) = H_p(4,N4)$$  \hspace{1cm} (14)

From continuity we have,

$$V_p(4,N4) = \left(\frac{D_5}{D_4}\right)^2 V_p(5,1) + \left(\frac{D_6}{D_4}\right)^2 V_p(6,1)$$  \hspace{1cm} (15)

These three equations along with three characteristic equations (one for each pipe) determine the six unknowns, $H_p(4,N4)$, $V_p(4,N4)$, $H_p(5,1)$, $V_p(5,1)$, $H_p(6,1)$, and $V_p(6,1)$. 
4. **Pulser Boundary Condition**

There are two unknowns at the pulser piston, \( H_p(5,N5) \) and \( V_p(5,N5) \). One characteristic equation is available and the other necessary equation is simply

\[
V_p(5,N5) = L_o \sin \omega t
\]  

(16)

where \( L_o \) is the pulser stroke and \( \omega \) is the angular frequency. The pulser inputs a sinusoidal variation in flow to the system.

5. **Downstream End of Pipe 7**

Since pipe 7 is terminated in an orifice the orifice equation is used to determine the boundary condition equation. If \( H_o \) is the pressure head downstream of the orifice and \( D_7 \) and \( D_o \) are pipe 7 and orifice diameters respectively,

\[
V_p(7,N7) \left( \frac{\pi}{4} D_7^2 \right) = C_{DO} \left( \frac{\pi}{4} D_o^2 \right)^2 \left[ 2g(H_p(7,N7) - H_o) \right]^{1/2}
\]

(17)

\[
V_p(7,N7) = C_{DO} \left( \frac{D_o}{D_7} \right)^2 \left[ 2g(H_p(7,N7) - H_o) \right]^{1/2}
\]

(18)

Since the pressure at the throat of the cavitating venturi is vapor pressure the pressure head, \( H_o \), can be determined from

\[
V_p(7,N7) = C_{DV} \left( \frac{D_v}{D_7} \right)^2 \left[ 2g(H_o - H_v) \right]^{1/2}
\]

(19)

\[
H_o = \frac{1}{2g} \left( \frac{D_7^2}{C_{DV}D_v} \right)^2 \left( \frac{D_7^2}{C_{DV}D_v} \right)^2 + H_v
\]

(20)
Equations (18) and (20) yield the desired boundary equation

\[ V_p(7,N7) = C_{DO} \left( \frac{D_0}{D_7} \right)^2 \left[ \frac{2g(H_p(7,N7) - H_v)}{1 + \left( \frac{C_{DO}}{C_{DV}} \right)^2 \left( \frac{D_0}{D_v} \right)^4} \right]^{1/2} \]  

(21)

where \( C_{DO} \) and \( C_{DV} \) are orifice and cavitating venturi discharge coefficients, \( D_v \) is the venturi throat diameter and \( H_v \) is the vapor pressure of the propellant in feet of head.
Referring to characteristic Equation (1), the friction term can be written
\[
\frac{1}{2} (fV_c^2) \frac{\Delta t}{D} = \rho \left( \frac{\Delta H}{\Delta X} \right) \Delta t
\]  
(22)

where \( \Delta H \) is the pressure head drop in the distance \( \Delta X \). Since internal losses in a pump are reflected in the pump head rise the friction term should not appear in the pump (pipe 6) equations. Instead, it is readily seen from Equation (22) that the term
\[
\rho \left( \frac{\Delta H_p}{L_p} \right) \Delta t
\]  
(23)

can be substituted for the friction term in the pipe 6 equations but with opposite sign to represent the pump head rise. \( L_p \) is the length of the pump flow path and \( \Delta H_p \) is the pump head rise. The characteristic equation for pipe 6 corresponding to Equation (1) is then
\[
V_p = \frac{1}{2} \left[ (V_R + V_S) + \rho (H_R - H_S) / \kappa_c + 2 \rho \left( \frac{\Delta H_p}{L_p} \right) \Delta t \right]
\]  
(24)

Equations (2) through (6) do not change because of the pump head rise and will apply to pipe 6.

The steady state pump head rise is a function of both the pump inlet pressure and flowrate as is shown on Figure 3. It was assumed that for transient conditions the head rise could be determined from these steady state characteristic curves. It was also assumed that affects due to variations in the pump speed were negligible.
Equations for the characteristic curves (Figure 3), determined by curve fitting methods, were used to compute the head rise, $\Delta H_p$, for particular values of inlet pressure and flowrate. The equation for $\Delta H_p$ is

$$
\Delta H_p = \Delta H_{po} - B_0(V_p(6,1) - V_o)^2 - \left( \frac{B_1}{B_2 + B_3} \frac{(H_p(6,1) - H_{po})}{H_{po}} \right)
$$

(25)

In this equation $\Delta H_{po}$, $B_0$, and $V_o$ are constants determined from the steady state head rise versus flowrate curve and $H_{po}$, $B_1$, $B_2$, and $B_3$ are constants determined from the steady state head rise versus inlet pressure curve.

The cavitation of the pump inlet impeller has a large effect on the fluid transients in the suction system. Tests at the Martin-Marietta Corporation (Denver Division) have shown that a region of cavitation can extend in the pump inlet pipe as far as from three to four feet upstream of the inlet to the oxidizer pump. This cavitation region drastically lowers the pressure-wave velocity in the inlet pipes and therefore lowers the quarter wave resonant frequency of the entire pump feed system. Since there is no way of computing the effect of this cavitation, the pressure wave velocity near the pump has to be approximated from test data. In this case, the quarter wave resonant frequency of each feed line used in the analysis was the value measured in the tests and pressure wave velocities for the feed system pipes were derived from
these measured values. It is also possible to determine these resonant
frequencies from a spectrum analysis of pump inlet pressure measured
during engine test firings.

The fuel pump feed pipe is short and it was assumed therefore
that the cavitation affected the pressure wave velocity in the entire
pipe. The length of pipe from the tank outlet to the pump inlet will
be a quarter wave length. The average pressure wave velocity in the
pipe is therefore

\[ a_T = \tfrac{1}{4} f_{nf} L_T \]  \hspace{1cm} (26)

where \( f_{nf} \) is the quarter wave resonant frequency and \( L_T \) is the length
of the fuel pump feed pipe.

The oxidizer feed pipe is long and the cavitation will only
affect a small portion of the pipe. The pipe was therefore considered
as three pipes each with a different pressure wave velocity. In this
case they are denoted pipe 2, 3, and 4. The pressure wave velocity in
pipe 2 was computed using Equation (8), the pressure velocity in pipe
3 was taken as one half the value of pipe 2, and the pressure wave
velocity in pipe 4 was determined so that the system resonant fre-
quency would be equal to the measured value.

Since the friction loss is small, the impedance relations for
a lossless fluid pipe were used to determine the pressure wave velocity
in pipe 4. The surge impedance for pipe 2 is
and the impedance of the downstream end of pipe 2, since the impedance of the tank end is very small, is

\[ Z_2 = j \, Z_{o2} \tan \beta_2 \, L_2 \]  \hspace{1cm} (28)

where

\[ \beta_2 = \frac{2\pi \, f_{no}}{a_2} \]  \hspace{1cm} (29)

and \( L_2 \) is the length of pipe 2 and \( f_{no} \) is the quarter wave resonant frequency. Similarly, the relations for pipes 3 and 4 are

\[ Z_{o3} = \frac{a_3}{\frac{\pi}{4} \, D_3 \, g} \]  \hspace{1cm} (30)

\[ Z_3 = Z_{o3} \frac{Z_2 + j \, Z_{o3} \tan \beta_3 \, L_3}{Z_{o3} + j \, Z_2 \tan \beta_3 \, L_3} \]  \hspace{1cm} (31)

\[ \beta_3 = \frac{2\pi \, f_{no}}{a_3} \]  \hspace{1cm} (32)

\[ Z_{o4} = \frac{a_4}{\frac{\pi}{4} \, D} \]  \hspace{1cm} (33)

\[ Z_4 = Z_{o4} \frac{Z_3 + j \, Z_{o4} \tan \beta_4 \, L_4}{Z_{o4} + j \, Z_3 \tan \beta_4 \, L_4} \]  \hspace{1cm} (34)

\[ \beta_4 = \frac{2\pi \, f_{no}}{a_4} \]  \hspace{1cm} (35)
Since $Z_4$ represents the impedance of the entire feed system at the pump inlet, this impedance will be maximum at the quarter wave resonant frequency $f_n$. Therefore, the denominator of Equation (34) will be zero at the frequency $f_n$ which provides the expression from which the pressure wave velocity $a_4$ can be obtained.

$$Z_{o4} + j Z_3 \tan \beta_4 L_4 = 0$$  \hspace{2cm} (36)

Using the first two terms of the tangent series and the expressions for $Z_4$ and $\beta_4$, Equation (36) becomes

$$a_4^4 - \frac{1}{2} |Z_3|(\pi^2 a_4^2 g f_{no} L_4) a_4^2 - \frac{2}{3} |Z_3|(\pi^4 a_4^2 g f_{no}^3 L_4^3) = 0$$  \hspace{2cm} (37)

which yields

$$a_4 = \left\{ 2.46 f_{no} L_4 D_4^2 g |Z_3| \left[ 1 + \sqrt{1 + \frac{10.7 f_{no} L_4}{D_4^2 g |Z_3|}} \right] \right\}^{1/2}$$  \hspace{2cm} (38)

This is an approximation for the effect of the cavitation. The most important aspect is that the pump feed lines in the analysis have the proper quarter wave resonant frequency.
THE COMPUTER PROGRAM

An abbreviated flow diagram for the solution of the fluid transients in the oxidizer system is illustrated in Figures 5a and 5b. The steady-state pressure heads, velocities, and the pressure wave velocity for each pipe are computed, stored, and printed for time \( t = 0 \). The velocity and pressure head for the interior sections of each pipe are computed from the same block of equations and the boundary points between the pipes are then computed from the boundary equations for time \( t + \Delta t \). The time increment \( \Delta t \) is chosen so that the interpolation points \( R \) and \( S \) lie within points \( A \) and \( C \) of Figure 4. The computed values are printed and stored for the next computation. The result is a time history of pressure head and velocity at each section of each pipe in the system.
Figure 5a. Computer Flow Diagram.
Figure 5b. Computer Flow Diagram (Continued).
RESULTS OF THE ANALYSIS

The results of the analysis compared with test results are shown in Figures 6 through 9. Figures 6 and 8 illustrate the ratio of the amplitude of the pump inlet pressure oscillation to the corrected acceleration amplitude of the pulser versus frequency. The pulser acceleration amplitude is corrected by the ratio of the flow area of the pulser to the flow area of the pump inlet pipe. These curves show a good agreement of the analysis results to test data.

Curves are shown in Figures 7 and 9 which compare the ratio of the amplitude of the pump discharge oscillation to the amplitude of the pump inlet oscillation. These ratios depend upon the pump dynamic characteristics. The agreement is fairly good which shows that the pump steady state characteristic curves are adequate for use in dynamic problems. The test data was quite non-linear for the fuel pump around the resonant frequency of 12 cps which could account for the deviation of the analysis results from the data around this frequency.

Curves are also shown in Figures 7 and 9 which compare the pump discharge pressure oscillation amplitude to the amplitude of the venturi inlet pressure oscillation. The analytical results compare well with the data which substantiates the analytical representation of the pump discharge systems.

Figure 9. Fuel Pump Pressure Ratio and Discharge System Pressure Ratio.
COMBINING THE PROPELLANT SYSTEMS WITH THE SUPPORTING STRUCTURE

A simplified block diagram to illustrate how the propellant system analysis can be combined with the supporting structure is shown in Figure 10. The fuel and oxidizer injector outflow oscillations as computed above are converted to a thrust oscillation by use of the engine thrust relations. The pump and tank motions which excite the propellant systems are computed from the structure dynamic equations of motion from this known thrust oscillation. From the pump motion the injector outflow oscillation is computed which completes the closed loop self excited system.

To determine the stability of this system the loop can be opened at the input to the structure and a conventional open loop stability analysis can be done. Since the scope of this paper is the analysis of the propellant systems, the stability problem will not be presented in any further detail.
Figure 10. Diagram of Combined Propellant System, Engine, and Structure Analysis.
CONCLUSIONS

The transient flow in a liquid rocket engine propellant feed system including turbopumps can be predicted when the effect of the pump cavitation on the resonant frequency of the system is known. The steady state pump characteristic curves (head rise as functions of flow rate and inlet pressure) were found adequate for the transient problem. The pump transient pressure ratio, defined as the amplitude of the discharge pressure oscillation per unit of inlet pressure oscillation, is predictable.
