

SEPTEMBER 2007

THE REVERSAL OF THE RELATION BETWEEN ECONOMIC GROWTH AND HEALTH PROGRESS: SWEDEN IN THE 19TH AND 20TH CENTURIES — SUPPLEMENTARY MATERIALS

José A. Tapia Granados¹ and Edward L. Ionides²

The tables and figures in this document supplement the data presented in the tables and figures in our paper “The reversal of the relation between economic growth and health progress: Sweden in the 19th and 20th centuries.” We hope they will facilitate the understanding of our conclusions to any reader who wants to go beyond the evidence presented in the printed paper. We have also included here the raw data we used (table S-0), so that our analysis can be reproduced.

The twenty seven tables and five figures in these SUPPLEMENTARY MATERIALS are numbered with an S as prefix, to differentiate them from the six tables and two figures in the paper numbered without letter prefix, and from the table A1 and the figure A1 in the appendix of the paper.

In these tables and figures we often present results using GDP growth as the indicator of economic growth, while in the paper, for the sake of consistency, we used the growth of GDP per capita as the measure of economic growth. Since both indicators correlate strongly, the results using one or the other are quite similar. In some analysis we found effects of GDP growth on age-and-sex-specific mortality in the 20th century that were marginally significant, with *P* values between 0.05 and 0.10. However, in these models, *P* values went slightly above 0.10 when the growth of GDP per capita instead of GDP growth was used as the regressor. In general, regression estimates show the effect of GDP growth on mortality as slightly stronger than the effect of GDP per capita growth.

We have also used, in many tables presented in these supplementary materials, the relative decline in longevity shortfall as an indicator of health progress. This indicator, proposed by

¹ Institute of Labor and Industrial Relations, University of Michigan, 1111 East Catherine Street, Ann Arbor, MI 48109-2054. E-mail: jatapia@umich.edu.

Amartya Sen, is the annual relative decline in the difference between the observed longevity (life expectancy at birth) and an arbitrarily chosen longevity target. Therefore, assuming that 90 is the target of longevity to be reached, the mortality shortfall is $90 - e_{0,t}$, where $e_{0,t}$ is life expectancy at birth for year t (we repeated some analyses with longevity shortfall computed with 100 as the target for longevity, obtaining very similar results). We computed the relative progress in longevity shortfall as the negative difference of the natural logarithm of longevity shortfall, that is, $-\Delta \ln (90 - e_{0,t}) = -[\ln (90 - e_{0,t}) - \ln (90 - e_{0,t-1})]$. Using the relative decline in longevity shortfall as the measure of health progress, an increase of one year and a half in longevity from 60 to 61.5 years would be a progress equivalent to a one-year increase from 70 to 71.

The structure of this set of supplementary materials is as follows. The raw data are included in table S-0. Detailed descriptive statistics of the variables used in the investigation are in table S-1. Tables S-2 and S-3 present the parameter estimates of regressions in which health progress is modeled as a function of GDP growth and the interactions of GDP growth either with time or with the level of GDP per capita. Tables S-4 and S-5 are just expanded versions of tables 1 and 2 in the paper, including R^2 and AIC values, as well as results for specifications that were suppressed in table 2. In table S-6, zero-lag correlations between health progress and economic growth are presented, and tables S-7 to S-9 are estimates of lag regressions in which health progress is modeled as a function of coincidental and lagged values of economic growth. In table S-10, health progress during the years 1911–1999 is modeled as a function of coincidental and lagged values of unemployment. Tables S-11 to S-16 present correlations between moving averages of health indicators and economic indicators, exploring the coincidental or lag effects of economic growth on health progress. Parameter estimates of lag regressions to explore the potential lagged effects of health progress on economic growth are in table S-17, while table S-18 presents correlations exploring the same issue. Tables S-19 and S-20 show correlations between health progress and economic growth, the latter indexed by GDP growth from two different sources, and also by GDP per capita growth. Results of Granger-causality tests are shown in tables S-21 to S-24, and tables S-25 and S-26 are an expanded version of table A1, including correlations between moving averages. Figures S-1 and S-2 are descriptive statistics, figure S-3 shows some results of spectral analysis, and figures S-4 and S-5 illustrate the reversal of the relation between economic growth and health progress with plots of moving averages. In the final section of this supplementary material, several estimates of the size of the macroeconomic effect on health progress are presented.

Table S-O. Raw data used in the analysis. See sources in the text. GDP and GDP per capita are indexed to 100 in 1930, the GDP deflator is 100 for 1910-1912 (F= females, M = males)

Year	Age-specific mortality rates per thousand population (per 1000 births in infant mortality)						Gross domestic product						GDP deflato r	Gener al crop index			
	Mortality at ages 15-24			Mortality at ages 35-54			Mortality at ages 70-89			Life expectancy at birth							
Infant mortality	Total	F	M	Total	F	M	Total	F	M	F	M	Total	Per capita	Total

Min	6.9	26.5	24.4	28.6	4.1	39.1	55.2	22.2	217.9	270.1	162.0	5532.9	6760.0	4667.5			
Max	625.6	78.8	76.2	81.5	232.0	1420.9	1645.2	1210.8	3023.7	3333.3	2751.1	17496.3	17786.9	17293.7			

Note: SD is standard deviation, GDP is volume GDP indexed to 100 in 1930; life expectancy is in years; infant mortality is in annual deaths per 100,000 population. The sample size is close to 200 for all series.

Table S-1 (Cont.). *Descriptive statistics**B. Variables in annual change*

Variable	Years	Mean	SD	Minimum	Maximum
GDP growth ($\Delta \ln \text{GDP}$)	1801– ca. 1998	2.3	3.5	- 8.9	11.7
	1801– 1850	1.1	3.4	- 7.0	7.0
	1851– 1900	2.3	3.4	- 8.8	11.7
	1901– 1950	3.0	4.2	- 8.9	10.9
	1951– ca. 1998	2.6	2.4	- 2.4	8.6
GDP per capita growth ($\Delta \ln \text{GDP per capita}$)	1801– ca. 1998	1.6	3.3	- 8.1	10.6
	1801– 1850	0.4	2.8	- 6.5	7.0
	1851– 1900	1.6	3.4	- 7.4	10.6
	1901– 1950	2.4	4.1	- 8.1	9.7
	1951– ca. 1998	2.0	2.4	- 3.4	7.7
Inflation ($\Delta \ln d$, where d is the GDP deflator)	1801– ca. 1998	2.4	6.5	- 25.0	36.9
	1801– 1850	1.6	5.9	- 10.1	21.3
	1851– 1900	0.7	4.9	- 13.2	12.1
	1901– 1950	2.1	9.3	- 25.0	36.9
	1951– ca. 1998	5.4	3.9	- 1.9	19.4
Rate of decline in longevity shortfall ($-\Delta \ln [90 - e_{0,t}]$, where e_0 is life expectancy at birth)	1801– ca. 1998	0.9	5.1	- 25.5	18.3
	1801– 1850	0.5	6.4	- 15.3	18.3
	1851– 1900	0.4	5.5	- 14.6	14.3
	1901– 1950	1.4	5.5	- 25.5	18.2
	1951– ca. 1998	1.2	1.5	- 1.9	5.2
Annual increase in life expectancy at birth ($\Delta e_{0,t}$)	1801– ca. 1998	0.20	2.33	- 9.05	8.64
	1801– 1850	0.10	3.46	- 8.50	8.64
	1851– 1900	0.13	2.58	- 7.56	7.41
	1901– 1950	0.38	1.85	- 9.05	6.71
	1951– ca. 1998	0.16	0.22	- 0.32	0.55
Rate of decline in infant mortality ($-\Delta \ln m_{<1,t}$)	1801– ca. 1998	2.1	8.6	- 26.8	24.4
	1801– 1850	1.0	11.0	- 26.8	20.6
	1851– 1900	0.8	9.8	- 20.7	24.4
	1901– 1950	3.1	7.1	- 10.6	23.3
	1951– ca. 1998	3.7	5.0	- 5.5	14.0
Rate of decline in mortality 15– 24 ($-\Delta \ln m_{15-24,t}$)	1801– ca. 1998	1.5	13.7	- 82.5	72.5
	1801– 1850	0.5	15.9	- 47.1	44.1
	1851– 1900	- 0.1	10.8	- 38.9	23.9
	1901– 1950	3.6	17.8	- 82.5	72.5
	1951– ca. 1998	1.8	7.7	- 10.9	18.8
Rate of decline in mortality 35– 54 ($-\Delta \ln m_{35-54,t}$)	1801– ca. 1998	1.1	10.0	- 42.8	50.8
	1801– 1850	0.5	15.1	- 33.7	50.8
	1851– 1900	0.9	9.3	- 20.2	28.8
	1901– 1950	1.9	8.9	- 42.8	33.8
	1951– ca. 1998	1.2	2.4	- 3.3	7.3
Rate of decline in mortality 70– 89 ($-\Delta \ln m_{70-89,t}$)	1801– ca. 1998	0.5	7.1	- 18.8	18.8
	1801– 1850	0.7	10.0	- 18.8	18.8
	1851– 1900	0.3	7.7	- 15.6	15.1
	1901– 1950	0.3	6.1	- 11.6	16.3
	1951– ca. 1998	0.9	2.6	- 4.5	7.5

Note: All numbers are annual rates in percentage, except the annual gain in life expectancy, which is in years

Table S-2. Parameter estimates of models in which annual health progress, measured as $-\Delta \ln h_b$, is regressed on a constant, time t , GDP growth g , and the interaction of time and economic growth, $g \cdot t$. Standard errors are in parentheses following parameter estimates. For the explanation of the tipping point, see text in the paper

Sample	Health indicator, h	Economic growth, g	Interaction $g \cdot t$	Tipping point

Table S-9. Regression results in models $H_t = \alpha + \sum_{i=0}^k \beta_i \cdot g_{t-i}$ in which sex specific health progress H_t (as measured either by the annual gain in life expectancy or by the rate of decline in mortality at specific ages) is regressed on a constant and growth of GDP per capita g in the same year ($k = 0$) or lagged up to two years ($k = 2$). M and F indicate if the sex-specific health indicator used as outcome variable is for males or females, respectively.

^a The stars following the correlations in these two columns indicate levels of statistical significance assuming correlations computed between series in which adjacent observations are independent. Since that assumption is false, the stars must be interpreted as just indicating that the correlation is “strong.”

Table S-26. Correlations between the general crop index and health progress. Correlations computed between annual series or 5- and 10-year moving averages of the general crop index and health progress as measured by the rate of growth in life expectancy or the rate of decline in age-specific mortality.

Variables correlated	Period	Annual	Moving averages ^a	
		series	Five year	Ten year
Crop index and rate of change in life expectancy	1801-1850	0.14	-0.02	-0.08

^a The stars following the correlations in these two columns indicate levels of statistical significance assuming correlations computed between series in which adjacent observations are independent. Since that assumption is false, the stars must be interpreted as just indicating that the correlation is “strong.”

Figure S-1. GDP growth, inflation, unemployment (as percent of economically active population), and life expectancy at birth (females, total, and males) in 19th and 20th century Sweden. Except for the line plot for the unemployment rate, all plots are 15-year centered moving averages.

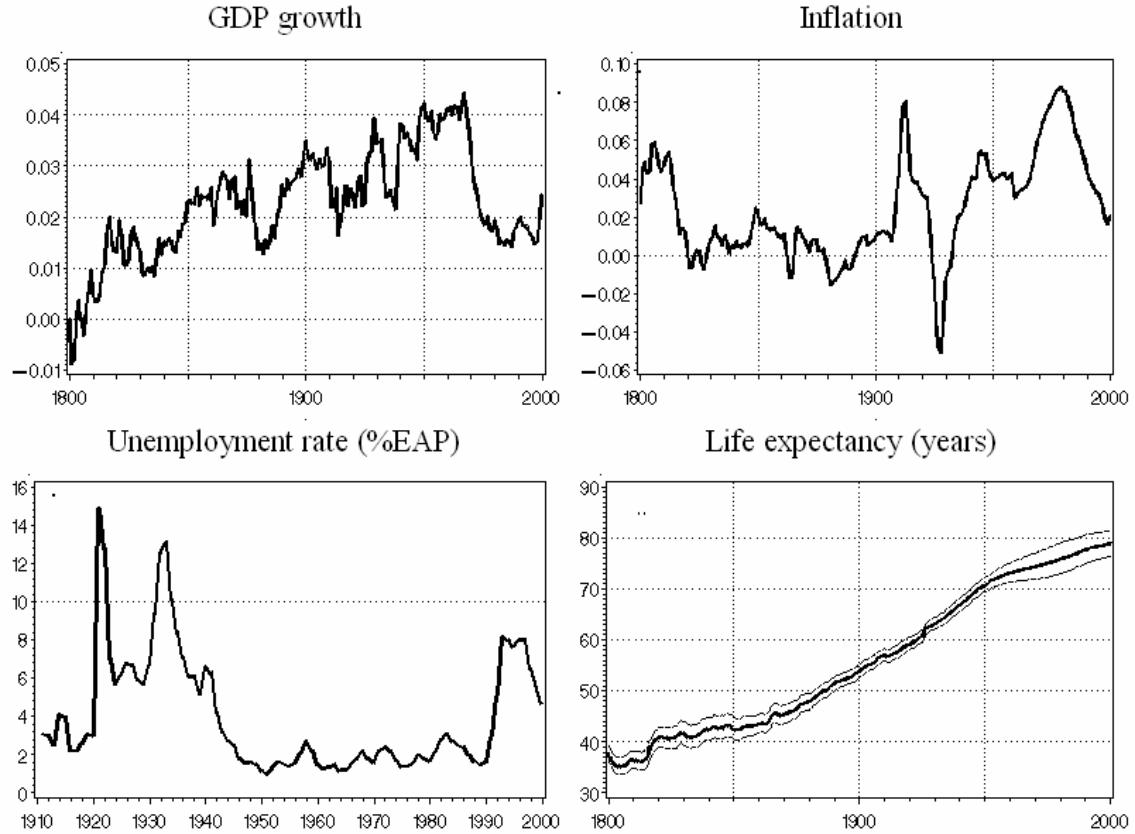

Figure S-2. Health progress in 19th and 20th century Sweden as measured by the annual decline in the natural logarithm of four health indicators: the longevity shortfall (the difference between 90 and life expectancy at birth), and age-specific mortality rates at ages 15-24, 35-54, and 70-89.

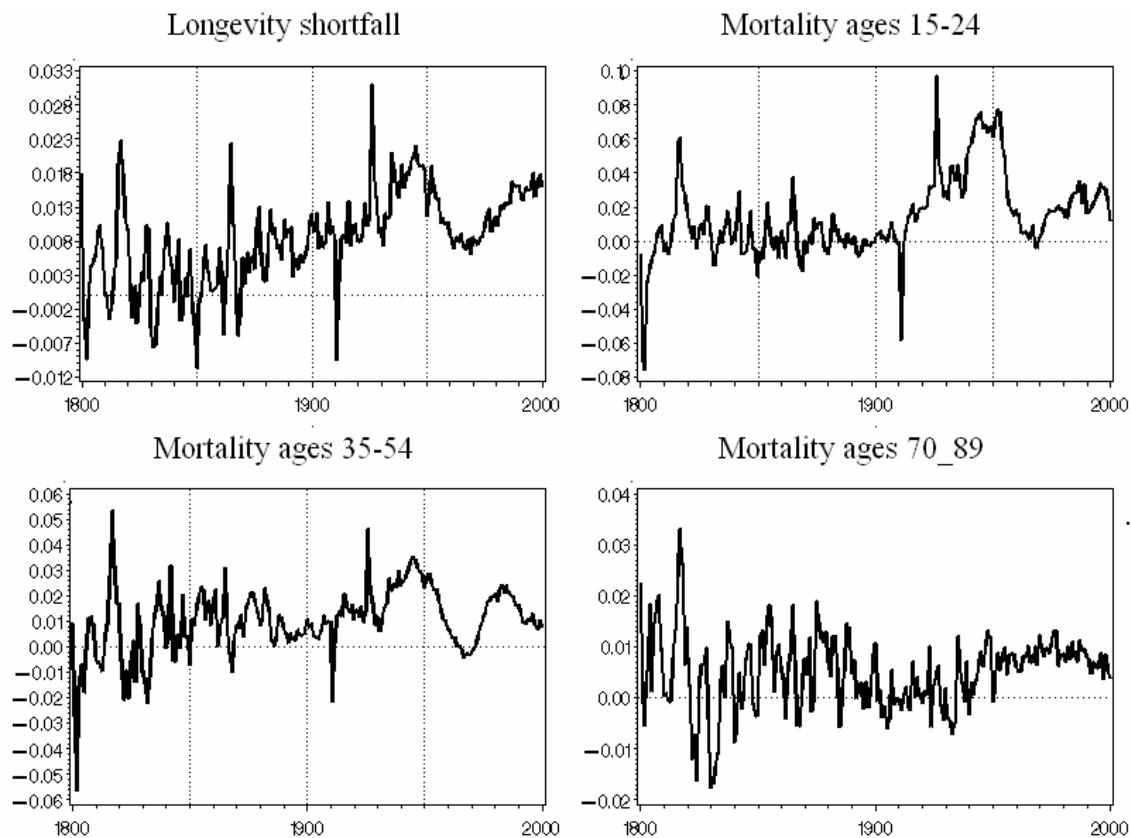

Figure S-3. Spectral analysis for the decline in mortality 35-54 and GDP growth. In the horizontal axis the period is in years. Dotted lines are 95% confidence limits.

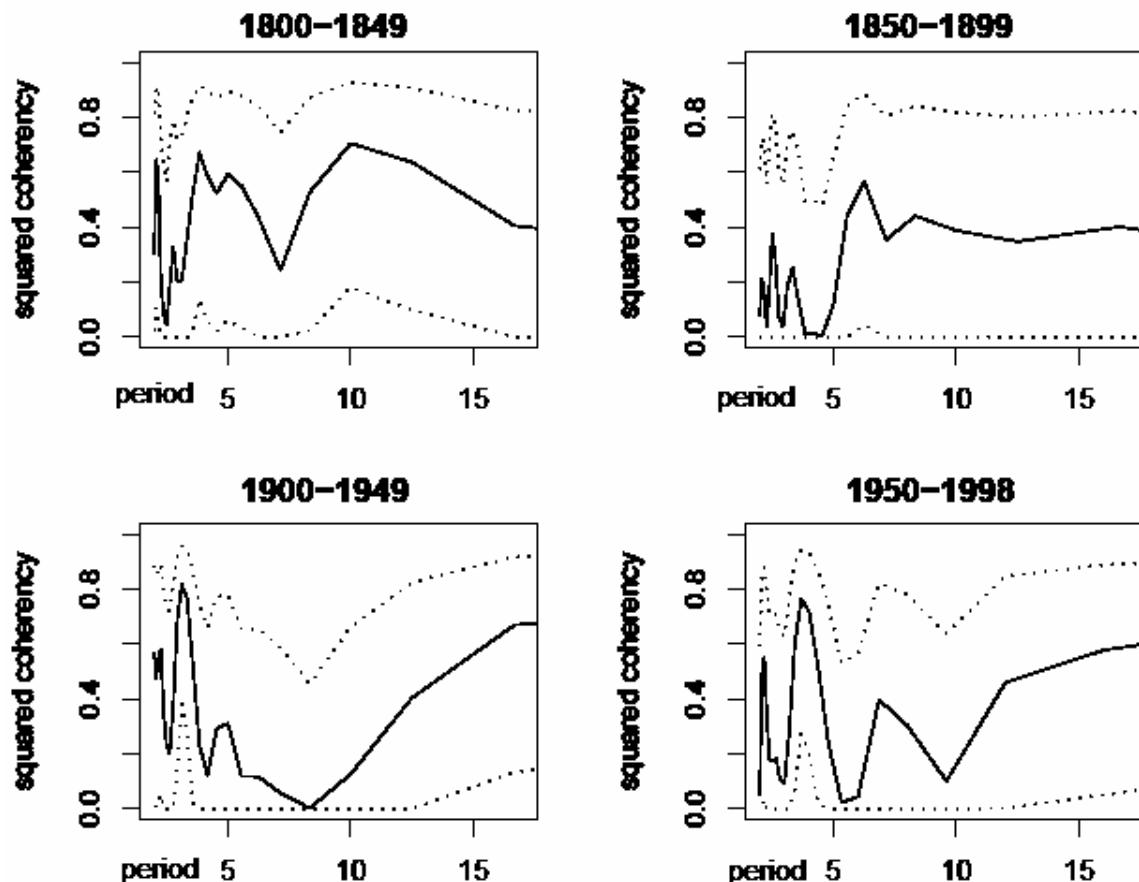

Figure S-4. GDP growth (g , thick line) and rate of change of mortality at ages 35-54 in 19th and 20th century Sweden. Both variables are transformed into 5-year centered moving means. Scales in percentages. Compare with figure 2 in the paper. They both reveal the same pattern of reversal of the relation between economic growth and health progress

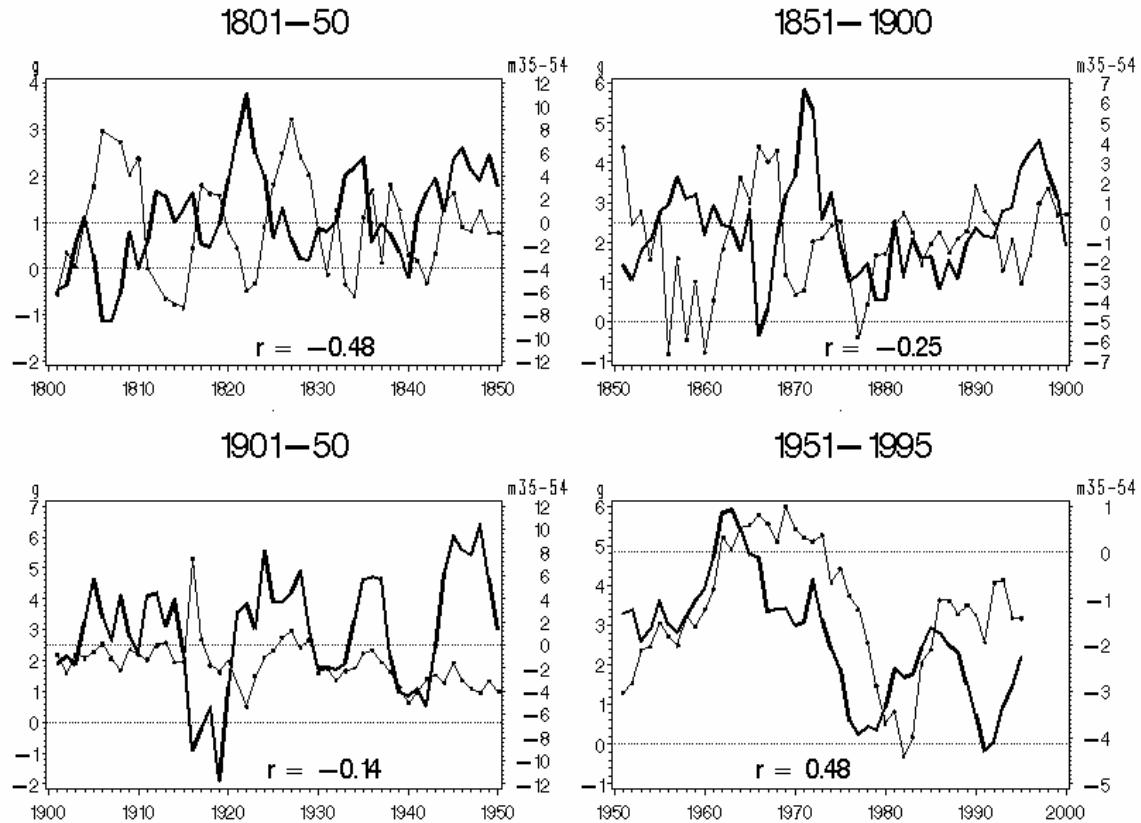

Figure S-5. GDP growth (thick line) and rate of change in life expectancy at birth (e_0) in Sweden, 1800–1995; both series are centered 5-year moving averages of year-to-year percent change. Note how the fluctuations of the rate of change in life expectancy dampen as time passes (the scale for e_0 is different in the 1951–1995 panel, where e_0 has always a positive rate of change), with the last strong drop in life expectancy caused by the world flu pandemics in 1918–1919 (third panel).

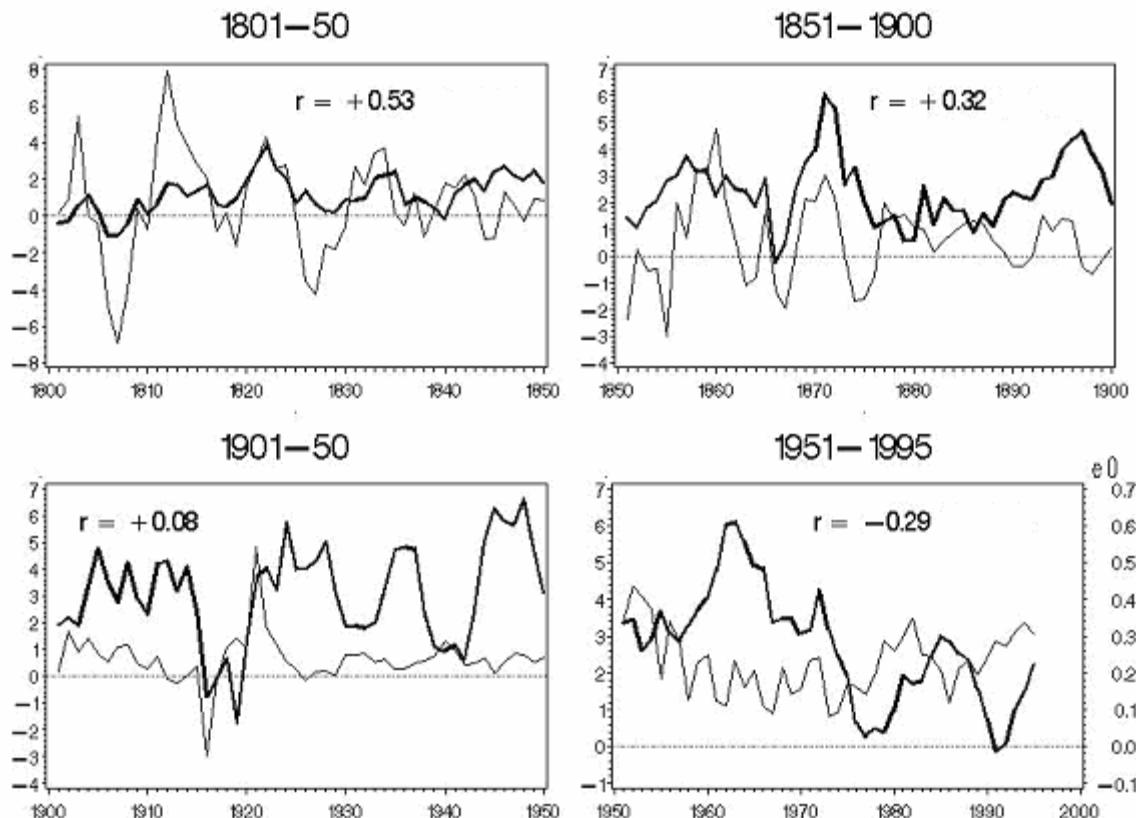

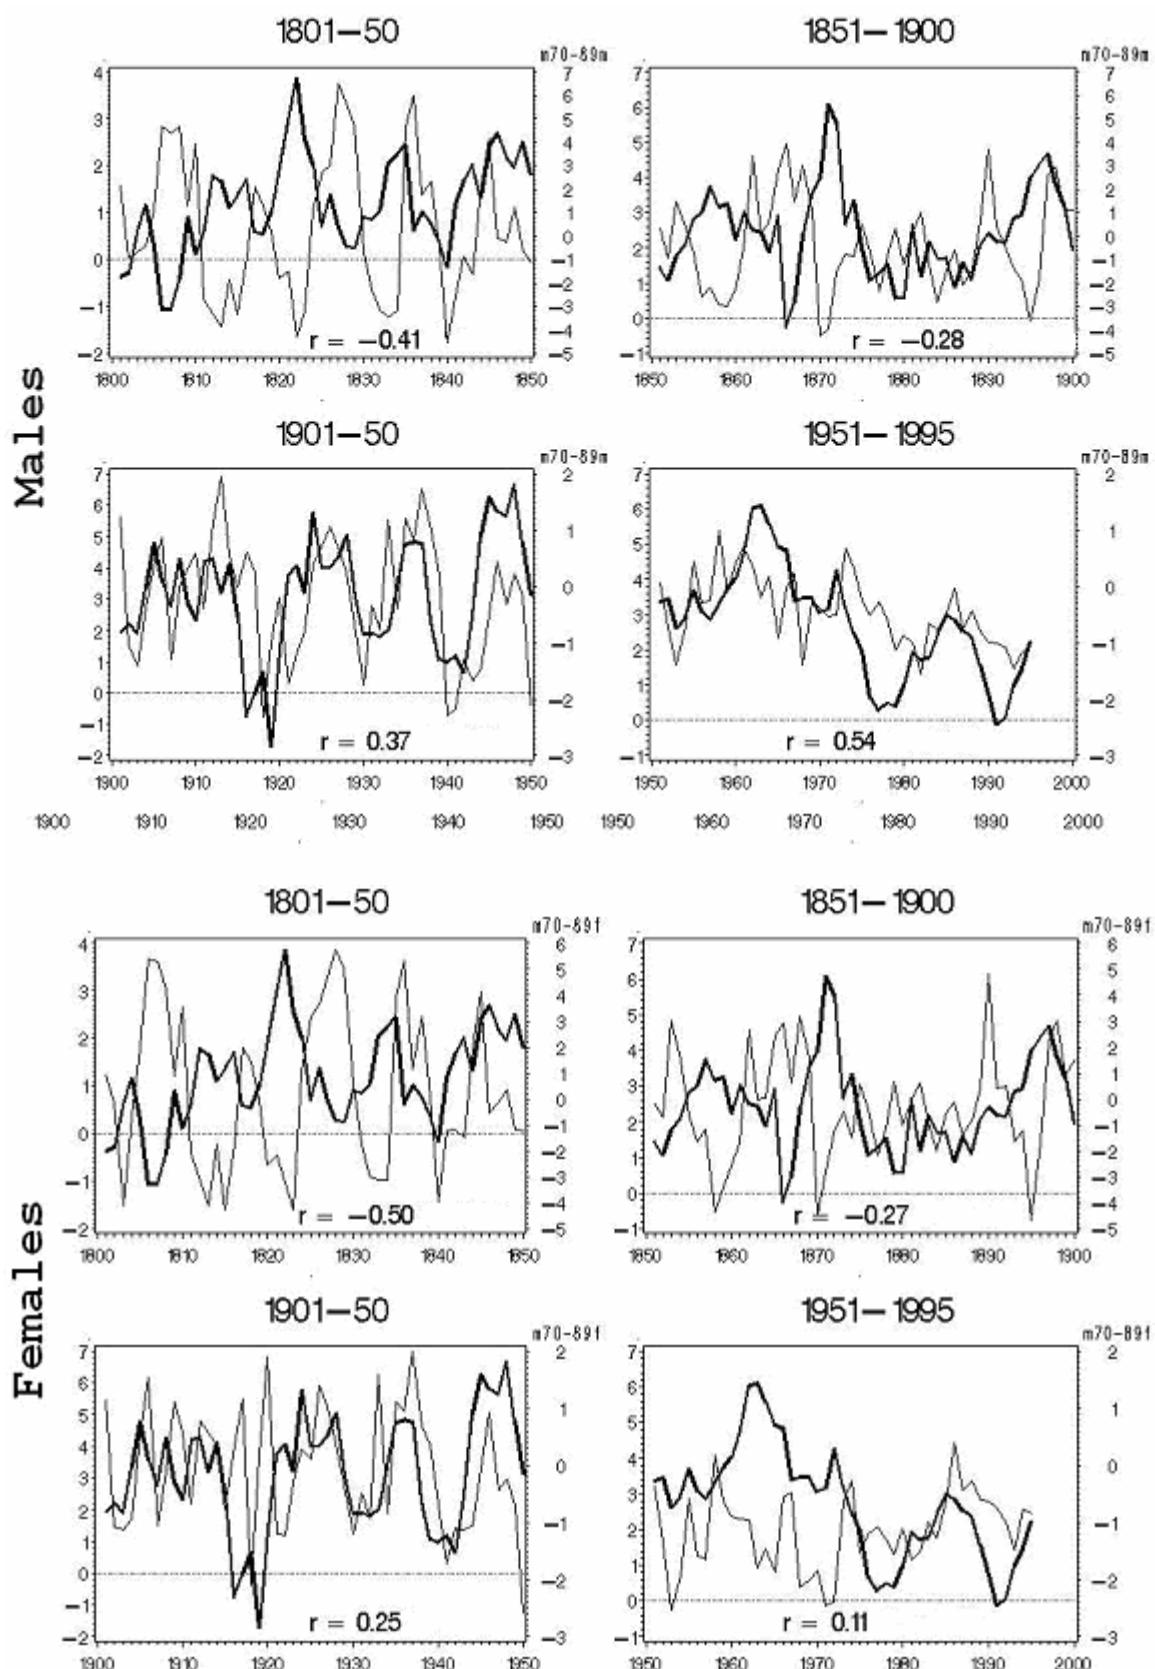

Figure S-6. GDP growth (thick line) and rate of change of sex-specific mortality at ages 70–89, both as centered 5-year moving average of year-to-year percent change.

An estimation of the size of the macroeconomic effect on health progress. In the years 1911–1999 the unemployment effect on gains in life expectancy (see table 4) is given by the equation (standard errors in parenthesis below parameter estimates)

$$\Delta e_{0,t} = 0.225 + 0.104 \Delta u_t - 0.013 \Delta u_{t-1} + 0.217 \Delta u_{t-2} \quad [1]$$

$$(0.145) \quad (0.088) \quad (0.085) \quad (0.089).$$

Therefore, assuming that there is no change in unemployment for three consecutive years, so that $\Delta u_t = \Delta u_{t-1} = \Delta u_{t-2} = 0$, the expected annual gain in life expectancy at birth at year t would be 0.225 years. Three years with consecutive increases in the unemployment rate of 1 percentage point each would make $\Delta u_t = \Delta u_{t-1} = \Delta u_{t-2} = 1$, so that the expected increase in life expectancy would be $0.225 + 0.104 - 0.013 + 0.217 = 0.533$, a gain 2.4 times greater than in conditions of stable unemployment.

For the model restricted to the years 1951–1999, the unemployment effect on gains in life expectancy is given by

$$\Delta e_{0,t} = 0.154 - 0.029 \Delta u_t + 0.106 \Delta u_{t-1} - 0.026 \Delta u_{t-2} \quad [2]$$

$$(0.033) \quad (0.054) \quad (0.062) \quad (0.025).$$

Therefore, without change in unemployment for three consecutive years, $\Delta u_t = \Delta u_{t-1} = \Delta u_{t-2} = 0$, and the expected annual change in life expectancy at birth at year t is 0.154 years. Three years with consecutive increases in the unemployment rate of 1 percentage point each would make $\Delta u_t = \Delta u_{t-1} = \Delta u_{t-2} = 1$, so that $\Delta e_{0,t} = 0.154 - 0.029 + 0.106 - 0.026 = 0.205$ and the expected increase in life expectancy would be 33% greater than in conditions of constant unemployment.

For the model restricted to the years 1911–1950 the unemployment effect on gains in life expectancy is given by

$$\Delta e_{0,t} = 0.351 - 0.122 \Delta u_t - 0.07 \Delta u_{t-1} - 0.242 \Delta u_{t-2} \quad [3]$$

From equations [2] and [3] it is easy to compute the change in unemployment in three successive years ($\Delta u_t = \Delta u_{t-1} = \Delta u_{t-2}$) that would reduce the annual gain in life expectancy to zero: that value is -3.02 for 1911–1959 and -0.98 for 1950–1999. The models therefore predict that for an interruption of the secular increasing trend in life expectancy, there would need to be three consecutive equal drops of about one percentage point in unemployment in 1911–1950 and about three percentage point in 1950–1999.
