Final Report (Appendix II)

SPECIAL INVESTIGATION OF ASPHALT RECOVERED FROM MIXTURES
OF ORIGINAL AND RE-USED AGGREGATE FROM MICHIGAN
AND MINNESOTA SOURCES AFTER (n) TYPE EXPOSURE

R. A. Leger

Supervisor Laboratory Operations

W. M. Aldous

Project Engineer

Project 2249

THE OHIO OIL COMPANY
FINDLAY, OHIO

May 1957

The basic report consists of data from which it is possible to compare the behavior of the asphalts when mixed with different aggregate and subjected to various degrees of exposure. The proportions of the mixtures were practically identical. The exposures varied and have been identified by letter symbols (a) to (n). These are summarized on the title page of each table or graph and are included in the text of the basic report.

With the exception of exposures (k) and (l), which consisted of 60-day outdoor weathering, all were conducted under laboratory conditions and varied with respect to aggregate, temperature, and duration.

In general, it required the more severe laboratory exposures to develop pronounced contrast in the behavior of the three asphalts. In exposure (n), the aggregate was heated to 350°F and the asphalt to 300°F prior to mixing for 1 minute. The loosely spread mixture was heated for 180 minutes in a force-draft oven at 325°F. It was then cooled and the asphalt was recovered and tested. This test was the most severe of the series and was especially effective in changing the spot characteristics.

A limited number of (n) exposures were included in the initial testing in which spot characteristics were determined with Skelly "S" and straight xylene solvent. The severe exposure accelerated change in the asphalt and appeared to be useful in determining the cause of a previously observed reduction in the weight of the recovered asphalt from that initially incorporated in the mixture.

The degree of heterogeneity of the recovered asphalt, as reflected by its spot characteristics was explored by varying the percent of xylene in heptane solvent, in addition to the previously used Skelly "S" and straight xylene.

The results of all preceding extraction and recovery of asphalt from fresh aggregate mixtures indicated a universal decrease in the recovered weight. Subsequent tests of the recovered asphalt showed changes in the relative proportions of asphaltenes, oily constituents, and resins. This change was manifest in the decrease of the resin/asphaltene (R/A) ratio. The extraction and recovery of asphalt followed the procedure described by A.S.T.M. Designation: D762-49, "Standard Method of Test for Hot Extraction of Asphaltic Materials and Recovery of Bitumen by the Modified Abson Procedure." Special care was exercised to insure complete recovery. The sample was weighed to the nearest gram. The benzene solvent was recycled for one hour or more after benzene became apparently colorless, during which time the mixture was stirred and agi-

The University of Michigan • Engineering Research Institute

tated every 15 minutes. The extractor was thoroughly flushed with fresh benzene, all vessels and utensils washed, the collective solvent and included material recaptured, solvent distilled, and residue centrifuged and supercentrifuged.

It was considered possible that a small portion of the original asphalt was absorbed or adsorbed by the original aggregate, in which case such retention might modify the decrease in quantity and properties of the same fresh asphalt when combined with and recovered from aggregate reclaimed from previous mixtures.

The test data are tabulated on page 6 and the percent change in the physical properties is shown on page 7. The results of the spot tests, which constitute a major portion of this supplemental investigation, have been photographed and are included on pages 9 to 92.

Data from the tables are on page 5. The average of three tests for each asphalt is reported. The letters (O) and (R) signify the original and re-used aggregate, respectively. Test results appearing in the basic report relative to (n) exposure have been included. Their similarity to the supplemental test values is of interest.

Leonard asphalt will be reviewed separately. Penetration of asphalt recovered from the mixture of original Michigan aggregate was 0.40%, the softening point, 1.89%, and the softening point-penetration ratio was 9.06% less than for re-used. Although the difference is quite small, it is not as anticipated because the asphalt components presumably remaining on the re-used aggregate did not contribute in reducing the change. Only a minor difference may be noted in the spot characteristics of the asphalt recovered from original and re-used aggregate.

In the case of the Minnesota aggregate, the comparison between the characteristics of the asphalt recovered from original and re-used mixtures is more consistent with the initial hypothesis that the percentage change is reduced due to retention by the aggregate of some component of the asphalt. Penetration of asphalt from the re-used aggregate decreased 2.0%, softening point, 3.17%, and softening point-penetration ratio, 70.50%, as compared to the asphalt recovered from the original aggregate mixture. Only minor difference occurred in the spot tests.

There were greater changes in the asphalts recovered from Minnesota aggregate mixtures than in those recovered from Michigan aggregate. An inspection of the tabulated values will readily disclose this behavior with respect to penetration, softening point, softening point-penetration ratio and in the spot tests, particularly in the case of Skelly and above 25% xylene—75% heptane solvents.

The individual appraisal of Lion asphalt indicates decreases of 1.05%,

The University of Michigan • Engineering Research Institute

2.36%, and 20.06% in penetration, softening point, and softening point-penetration ratio, respectively, in the re-used aggregate mixtures as compared with the initial Michigan aggregate. With Minnesota aggregate the trend is partially reduced or reversed. Penetration increased 0.35%, softening point increased 0.47%, and softening point-penetration ratio decreased 0.17%. These differences are practically immaterial as are the variations in spot tests.

Test results on Trumbull asphalt mixtures with Michigan original and re-used aggregate indicate an appreciable change. A decrease of 6.59%, 6.96%, and 109.48% occurred in penetration, softening point, and softening point-penetration ratio, respectively, for asphalt recovered from re-used aggregate. Spot-test results are very similar with original and re-used aggregate. With Minnesota aggregate, the change is reversed. With the re-used aggregate the change was 1.55%, 4.27%, and 93.11% greater in penetration, softening point, and softening point-penetration ratio. There is little difference in spot-test results.

The following performance ratings of the three test asphalts were formulated by using the criterion of least change to indicate behavior under (n) exposure. Asphalt performance is compared by (1) best, (2) intermediate, and (3) least favorable. An arbitrary rating of +5 for negative spot, -2 for ring, -3 for trace, -4 for slightly positive, and -5 for positive spot were used to evaluate the results of the spot tests.

Rating of Leonard, Lion, and Trumbull Asphalt

Penet	Soft Pt	Soft Pt/ Pen Ratio	Skelly	100% Xylene	% Xylene in Heptane

The University of Michigan • Engineering Research Institute

The preceding table has been condensed below to facilitate interpretation of test results. The percent change of the asphalts with respect to penetration, softening point, and softening point-penetration ratio is listed in order of their performance. The arbitrary numerical ratings of spot tests for each condition and solvent have been added algebraically. For example, 3 negative spots are indicated by a value of +15, 3 positive spots by -15. A combination of 1 positive and 2 ring spots would have a value of -9 whereas 1 negative and 2 ring spots would be indicated by +1.

Penet	Michigan Aggregate			Original or Re-Used	Minnesota Aggregate		
	Soft Pt	Soft Pt/ Pen Ratio	Spot		Penet	Soft Pt	Soft Pt/ Pen Ratio
L	OL	L	L +29	Original	L	L	L
OL	L	OL	OL -14	Original	OL	OL	OL -43
OT	OT	OT	OT -53	Original	OT	OT	OT -62
<hr/>							
L	L	L	L +39	Re-used	L	OL	L
OT	OL	OT	OL -22	Re-used	OL	L	OL -50
OL	OT	OL	OT -52	Re-used	OT	OT	OT -72

Note: L = Lion Asphalt OL = Leonard Asphalt OT = Trumbull Asphalt

Based on (n) exposure, percent change in test values, and the arbitrary relative numerical scale for spots, evaluation of asphalt behavior may be in terms of performance as Lion, Leonard, and Trumbull, regardless of source or condition of aggregate.

With regard to spot test for asphalt recovered from Michigan aggregate mixtures, Lion asphalt improved, Leonard deteriorated, and Trumbull improved with re-used aggregate. With Minnesota aggregate, the spot scale values all deteriorated with re-used material. These results do not confirm the preliminary hypothesis that re-used aggregate might tend to reduce change in the asphalt.

Conclusions relative to the foregoing test results will be incorporated in the basic report.
