Reinforced Concrete - WSD

- Material Properties
- Stress in Beams
- Transformed Sections
- Analysis by WSD
- Design by WSD
Constituents of Concrete

- Sand
- Aggregate
- Cement
- Water

Fine aggregate (Sand) ≤ 1/4”

- ~ 3/8” aggregate
- limestone aggregate ~ 1.5”

Photos: CC:BY-SA Emadrazo (wikipedia)
http://creativecommons.org/licenses/by-sa/3.0/
Constituents of Concrete

- Sand
- Aggregate
- Water

Cement Types

- **Type 1**
  - normal portland cement. Type 1 is a **general use** cement.

- **Type 2**
  - is used for structures in water or soil containing moderate amounts of **sulfate**, or when heat build-up is a concern.

- **Type 3**
  - **high early strength**. Used when high strength are desired at very early periods.

- **Type 4**
  - **low heat** portland cement. Used where the amount and rate of heat generation must be kept to a minimum.

- **Type 5**
  - **Sulfate resistant** portland cement. Used where water or soil is high in alkali.

- Types IA, IIA and IIIA are cements used to make **air-entrained** concrete.
Workability

• Measured by the inches of “slump” of a molded cone of fresh mix.
  – range 1” to 4” with vibration
  – 2” to 6” without vibration

• Water/Cement Ratio
  – range 0.4 to 0.7
  – for strength: higher is weaker
  – for workability: higher is better

• Cement Content
  – LBS per cubic yard
  – range 400-800
  – dependent on aggregate
  – increases cost

Photos: CC:BY-SA Tano (wikipedia)
http://creativecommons.org/licenses/by-sa/3.0/
Reinforcing

- **Grade = Yield strength**
  - gr. 40 is 40 ksi
  - gr. 60 is 60 ksi

- **Size in 1/8 inch increments**
  - #4 is ½ inch dia.
  - #6 is ¾ inch dia.

- **Deformation Patterns**
  - add to bond with concrete

- **Spacing**
  - between bars
    - Bar diameter
    - 1”
    - 5/4 x max agg.
  - between layers
    - 1”
  - coverage
    - 3” against soil
    - 1.5”-2” exterior
    - 3/4” interior

Curing

Strength increases with age. The “design” strength is 28 days.

Source: Portland Cement Association
Strength Measurement

• Compressive strength
  – 12”x6” cylinder
  – 28 day moist cure
  – Ultimate (failure) strength

• Tensile strength
  – 12”x6” cylinder
  – 28 day moist cure
  – Ultimate (failure) strength
  – Split cylinder test
  – Ca. 10% to 20% of $f_c$
Young’s Modulus

- Depends on density and strength
  \[ E_c = w_c^{1.5} 33 \sqrt{f'_c} \]

- For normal (144 PCF) concrete
  \[ E_c = 57000 \sqrt{f'_c} \]

- Examples
  \[
  \begin{array}{ll}
    f'_c & E \\
    3000 \text{ psi} & 3,140,000 \text{ psi} \\
    4000 \text{ psi} & 3,620,000 \text{ psi} \\
    5000 \text{ psi} & 4,050,000 \text{ psi}
  \end{array}
  \]

Source: Ronald Shaeffer
Flexure and Shear in Beams

Reinforcement must be placed to resist these tensile forces.

In beams continuous over supports, the stress reverses (negative moment). In such areas, tensile steel is on top.

Shear reinforcement is provided by vertical or sloping stirrups.

Cover protects the steel.

Adequate spacing allows consistent casting.
Flexure – WSD Method

• Assumptions:
  – Plane sections remain plane
  – Hooke’s Law applies
  – Concrete tensile strength is neglected
  – Concrete and steel are totally bonded

• Allowable Stress Levels
  – Concrete = 0.45$f_c$
  – Steel = 20 ksi for gr. 40 or gr. 50
    = 24 ksi for gr. 60

• Transformed Section
  – Steel is converted to equivalent concrete.

\[ n = \frac{E_s}{E_c} \]
Flexure Analysis

Procedure:
1. Assume the section is cracked to the N.A.
2. Determine the modular ratio:
   \[ n = \frac{E_s}{E_c} \]
3. Transform the area of steel to equivalent concrete, \( nA_s \)
4. Calculate the location of the N.A. using the balanced tension and compression to solve for \( x \).
   \[ A_c x_c = A_t x_t \]
5. Calculate the transformed Moment of Inertia.
6. Calculate a maximum moment based first on the allowable concrete stress and again on the allowable steel stress.
7. The lesser of the two moments will control.

\[ M_c = \frac{f_c I_{tr}}{c_c} \]
\[ c_c = x \]
\[ M_s = \frac{f_s I_{tr}}{nc_t} \]
\[ c_t = d - x \]
Example – Flexure Analysis

1. Assume the section is cracked to the N.A.
2. Determine the transformation ratio, $n$
3. Transform the area of steel to equivalent concrete, $nA_s$

---

Source: University of Michigan, Department of Architecture
4. Calculate the N.A. using the balanced tension and compression to solve for $x$.

$$A_c x_c = A_t x_t$$
Example - Flexure Analysis  cont.

5. Calculate the transformed Moment of Inertia.

\[
I_c = \frac{bd^3}{3} = \frac{(12\text{ in})(6.73\text{ in})^3}{3} = 1247 \text{ in}^4
\]

\[
I_0 = A\bar{y}^2 = (2\text{ in}^2)(10.22\text{ in})^2 = 2820 \text{ in}^4
\]

(ASSUME MINUTE THICKNESS OF STEEL → NO \( \frac{bh^3}{12} \))

\[
I_{tr} = 4067 \text{ in}^4
\]
6. Calculate a maximum moment based first on the allowable concrete stress and again on the allowable steel stress.

7. The lesser of the two moments will control.

**Example – Flexure Analysis cont.**

**Concrete:** $f_c = 1.8\, \text{ksi}$

$$M = \frac{f_c I}{c} = \frac{(1.8\, \text{ksi})(4067\, \text{in}^4)}{6.78''} = 1080\, \text{ft-k} = 90\, \text{k}

**Steel:** $f_s = 20\, \text{ksi}$

$$M = \frac{f_s I}{c} = \frac{(20\, \text{ksi})(4067\, \text{in}^4)}{(10.22'')(a)} = 884\, \text{ft-k} = 74\, \text{k}

90\, \text{k} \rightarrow \text{Steel governs}

**Beam Capacity = 74\, \text{k}**

Source: University of Michigan, Department of Architecture
Effect of $\rho$

The behavior of the beam at failure (mode of failure) is determined by the relative amount of steel present – measured by $\rho$.

$\rho = 0$
No steel used. Brittle (sudden) failure.

$\rho_{\text{min}}$
Just enough steel to prevent brittle failure

$\rho < \rho_{\text{balance}}$
Steel fails first – ductile failure (desirable)

$\rho_{\text{balance}} = \rho_{\text{max}}$
Steel and concrete both stressed to allowable limit

$\rho > \rho_{\text{balance}}$
Concrete fails first – brittle failure (not desirable)
Calculate $\rho$ balance

Procedure:
1. Draw stress diagram using allowable stresses $f_c$ and $f_s/n$
2. Use similar triangles to find $x$ and $\bar{x}_s$
3. Find $\bar{x}_c = x/2$
4. Use moments of areas on transformed section to solve for $A_s$.
5. Calculate $\rho$ bal = $A_s/bd$

Stress Triangles:

\[
\frac{1.8 + 2.22}{17''} : \frac{1.8}{x} : \frac{2.22}{\bar{x}_s}
\]

\[x = 7.612'' \quad \bar{x}_s = 9.388''\]

\[\bar{x}_c = \frac{n}{2} = 3.804''\]

Moments of Areas:

\[A_c \bar{x}_c = nA_s \bar{x}_s\]

\[A_s = \frac{A_c \bar{x}_c}{n \bar{x}_s} = 4.11''^2\]

Balanced $\rho$

\[\rho_{bal} = \frac{A_s}{bd} = \frac{4.11}{12(17)} = 0.02017\]
“Internal Couple” Method

- Uses the internal force couple T & C to determine the moment
- Defines factors k and j that can be used to find depth of stress block and moment arm of couple
- Provides equations for analysis or design.

\[
\rho = \frac{A_s}{bd}
\]

\[
k = \sqrt{2\rho n + (\rho n)^2} - \rho n
\]

\[
j = 1 - \frac{k}{3}
\]

\[
f_c = \frac{2M}{bd^2kj}
\]

\[
f_s = \frac{M}{A_sjd}
\]

**Analysis:**

\[
M = Cjd
\]

\[
M = \frac{bkdf_c}{2} jd
\]

\[
M = Tjd
\]

\[
M = A_s f_s jd
\]

**Design:**

\[
A_s = \frac{M}{f_s jd}
\]

\[
bd^2 = \frac{2M}{f_c kj}
\]
Analysis by “Internal Couple”

Example:

1. Find \( \rho = \frac{A_s}{bd} \)
2. Find \( k \)
3. Calculate \( j \)
4. Calculate either force \( T \) or \( C \)
5. Calculate \( M \) using either \( T \) or \( C \)

\[
\rho = \frac{A_s}{bd} = \frac{3.0}{12 \times 17} = 0.0147
\]

\[
\rho n = 0.0147 \times 9 = 0.1324
\]

\[
k = \sqrt{2(0.1324) + 0.1324^2} - 0.1324
\]

\[
k = 0.3989
\]

\[
k d = 0.3989 \times 17 = 6.78''
\]

\[
j = 1 - \frac{k}{3} = 1 - \frac{0.3989}{3}
\]

\[
j = 0.867
\]

Assume steel controls:

\[
T = A_s f_s = 3.0 \times 20 = 60\ k
\]

\[
M = T j d = 60 \times (0.867) \times (17) = 884.4''\cdot k = 73.7''\cdot k
\]
Flexure Design

Procedure:

1. Determine load conditions.
   - choose material grade, $f'_c$
   - calculate $n = E_s/E_c$
   - estimate size, choose $b$ and estimate $d$
     
     \[
     \frac{1}{2} \approx \frac{b}{d} \approx \frac{2}{3}
     \]
     
     - determine loads (+ member DL)
     - calculate moment

2. Choose a target steel ratio, $\rho$.
3. Sketch the stress diagram with force couple.
4. Calculate $d$ based on the required moment.
5. Calculate $A_s$.
6. Choose bar sizes and spacing.
7. Choose beam size and revise (back to step 1 with new $b$, $d$ and $\rho$).
1. As a simplification the moment is given = 200 ft-k.

d will be determined based on the moment.

f'c is given as 4000 psi

n is found = 8.

Modular Ratio: \( n = \frac{E_s}{E_c} = \frac{29,000}{3,625} = 8 \)
Example – Flexure Design cont.

2. Steel ratio, As/bd is taken as balanced for this problem.

3. Using similar triangles, determine depth of reinforcement, D in relationship to depth of compression zone, x.

Calculate the compression zone resultant, $R_c$ in terms of $x$

$$R_c = \frac{f_c B x}{2}$$

4. Use the internal moment couple

$$M = R_c (D-x/3)$$

to solve for $x$ and $D$.

Source: University of Michigan, Department of Architecture
Example - Flexure Design  cont.

5. Calculate $A_s$ using
   \[ R_c = \frac{f_c (8) (x)}{2} = 12.6 \times \]
   \[ = 12.6 (9.0^\circ) \]
   \[ = 113.4 \text{kN} \]
   \[ R_t = R_c \]
   \[ R_t = A_s f_s \]
   \[ 113.4 \text{kN} = A_c (24 \text{ksi}) \rightarrow A_c = 4.73 \text{ in}^2 \]

7. Choose bar sizes and spacing.
   - Area $\geq A_s$
   - c.g. = D
   - must be symmetric
   - minimum spacing

8. Choose cover, recalculate dead load, iterate with new moment.
