Structural Continuity

- Continuity in Beams
- Deflection Method
- Slope Method
- Three-Moment Theorem

Continuous Beams

- Continuous over one or more supports
  - Most common in monolithic concrete
  - Steel: continuous or with moment connections
  - Wood: as continuous beams, e.g. long Glulam spans

- Statically indeterminate
  - Cannot be solved by the three equations of statics alone
  - Internal forces (shear & moment) as well as reactions are effected by movement or settlement of the supports

Source: University of Michigan, Department of Architecture
Deflection Method

- Two continuous spans
- Symmetric Load and Geometry

Procedure:
1. Remove the central support.
2. Calculate the central deflection for each load case as a simple span.
3. Set the resulting central deflection equal to the central reaction “deflection” upward, bringing the total central deflection back to zero.
4. Solve the resulting equation for the central reaction force.
5. Calculate the remaining two end reactions
6. Draw shear and moment diagrams as usual.

\[ EI\Delta_1 + EI\Delta_2 = 0 \]

Source: University of Michigan, Department of Architecture
Deflection Method Example:

Replace redundant reaction with point load, bringing reaction deflection to zero.
Deflection Method Example cont.: 

Write deflection equations and solve for middle reaction. Solve remaining reactions by summation of forces.
Deflection Method Example cont.: Complete the shear and moment diagrams.
Slope Method

- Two continuous spans
- Non-Symmetric Load and Geometry

Procedure:
1. Break the beam into two halves at the interior support.
2. Calculate the interior slopes of the two simple spans.
3. Use the Slope Equation to solve for the negative interior moment.
4. Find the reactions of each of the simple spans plus the M/L reactions caused by the interior moment.
5. Add all the reactions by superposition.
6. Draw the shear and moment diagrams as usual.

\[
M = \frac{3}{L_1 + L_2} \left[ EI\Theta_1 + EI\Theta_2 \right]
\]
Example of Slope Method:

Use slope formula to solve interior moment

\[ EI \theta_1 = \frac{Pl^2}{9} = \frac{27(24)^2}{9} = 1728 \]
\[ EI \theta_2 = \frac{Wl^2}{24} = \frac{48(24)^2}{24} = 1152 \]
\[ M = \frac{3}{L_1 + L_2} [EI \theta_1 + EI \theta_2] = \frac{3}{48} [2880] \]
\[ M = 180^k' \]
Example of Slope Method cont.:

Solve the end reactions by superposition of FBD’s
Example of Slope Method cont.:

Construct load, shear and moment diagrams.
Three-Moment Theorem

- Any number of spans
- Symmetric or non-symmetric

Procedure:

1. Draw a free body diagram of the first two spans.
2. Label the spans L1 and L2 and the supports (or free end) A, B and C as shown.
3. Use the Three-Moment equation to solve for each unknown moment, either as a value or as an equation.

\[ M_A L_1 + 2M_B (L_1 + L_2) + M_C L_2 = 6[EIA\theta_1 + EIA\theta_2] \]
Three-Moment Theorem (cont.)

Procedure:
4. Move one span further and repeat the procedure.
5. In a 3 span beam, the mid-moment from step 3 above (B), could now be solved using the two equations from step 4 and 3 together, by writing 2 equations with 2 unknowns.
6. Repeat as needed, always moving one span to the right and writing a new set of moment equations.
7. Solve 2 simultaneous equations for 3 spans, or 3 equations for more than 3 spans, to get the interior moments.
8. Once all interior moments are known, solve for reactions using free body diagrams of individual spans.
9. Draw shear and moment diagrams as usual. This will also serve as a check for the moment values.

\[
M_B L_2 + 2M_C (L_2 + L_3) + M_D L_3 = 6\left[EI\Theta_2 + EI\Theta_3\right]
\]
Three-Moment Theorem Example

\[
\begin{align*}
\text{FIRST EQUATION (AT 1, 2 AND 3):} & \quad M_A = 0, \quad L_1 = 12, \quad E_1 \theta_1 = \frac{W_1 l_1^2}{24} = \frac{48(12)^2}{24} = 288 \\
M_B &= M_2, \quad L_2 = 30, \quad E_1 \theta_2 = \frac{5 P l_2^2}{8} = \frac{5(60)(30)^2}{8} = 3333.3 \\
M_C &= M_3, \quad L_1 + L_2 = 42, \quad E_1 \theta_2 = E_1 \theta_3 = \left[ E_1 \theta_1 + E_1 \theta_2 \right] \\
M_A L_1 + 2M_B (L_1 + L_2) + M_C L_2 &= 6 \left[ E_1 \theta_1 + E_1 \theta_2 \right] \\
0(12) + 2 M_B (42) + M_3 (30) &= 6 \left[ 288 + 3333.3 \right] \\
M_2 &= 258.667 - 0.35714 M_3
\end{align*}
\]
Three-Moment Theorem Example (cont.)

\[ M_4 = M_2, \quad l_1 = 30, \quad E_1 \theta_1 = \frac{4P l^2}{81} = \frac{4(60)(30)^2}{81} = 2666.67 \]
\[ M_8 = M_3, \quad l_2 = 15, \quad E_1 \theta_2 = \frac{75 l^2}{24} = \frac{90(15^2)}{24} = 843.75 \]
\[ M_2(30) = 2M_3(45) = 0(15) = 6 \left[ 2666.67 + 843.75 \right] \]
\[ M_2 = 702.084 - 3M_3 \]

Simultaneous Solution:
\[ 258.667 - 35714M_3 = 702.084 - 3M_3 \]
\[ M_3 = 443.417 / 2.6428 = 167.779 \text{ K}^{-1} \]
\[ M_2 = 702.084 - 3(167.779) = 198.746 \text{ K}^{-1} \]
Three-Moment Theorem Example (cont.)
Three-Moment Theorem Example (cont.)

[Diagram showing Moment, Shear, and Deflection analysis for a beam with load cases.]
Three-Moment Theorem – 2 Spans

\[ M_A L_1 + 2 M_B (L_1 + L_2) + M_C L_2 = 6 \left( E I \Theta_1 + E I \Theta_2 \right) \]

Source: University of Michigan, Department of Architecture
Three-Moment Theorem – 3 Spans

\[ M_A L_1 + 2M_B \left( L_1 + L_2 \right) + M_C L_2 = 6\left[ EI \Theta_1 + EI \Theta_2 \right] \]
