I. Tetrahydrofolate as a carrier of one-carbon units

A. Obtaining folic acid - an essential vitamin

1. Dietary sources (green veggies, fortified cereals, liver) provide folic acid. Cleaved by enzyme 'conjugase' to remove extra glutamate residues, absorbed, reduced to dihydrofolate, then to tetrahydrofolate by Dihydrofolate Reductase (DHFR). DHFR inhibitors are useful antibiotics if they affect other organisms but not humans.

\[ \text{folic acid} \xrightarrow{\text{conjugase}} \text{dihydrofolate} \xrightarrow{\text{Dihydrofolate Reductase}} \text{tetrahydrofolate} \]

2. Inhibitors of DHFR are used therapeutically: e.g. methotrexate (cancer chemotherapy). Tumors that resist methotrexate sometimes have amplified the DHFR gene to compensate for the inhibitor.
3. Compounds that inhibit bacterial folate biosynthesis can be excellent antibiotics. Example: sulfa drugs like sulfanilamide:

![Para-aminobenzoic acid (PABA)](image)

![sulfanilamide](image)

**B. Main entry of one-carbon units - N⁵, N¹⁰ methylene tetrahydrofolate**

1) Serine conversion to glycine:

![Serine conversion](image)

2) Glycine conversion to CO₂ and NH₄⁺:

![Glycine conversion](image)

**C. Oxidation states of the one-carbon unit and inter-conversions**

(reversible reactions indicated by double-ended arrows)

![Oxidation states](image)
II. S-adenosylmethionine ('SAM', aka 'AdoMet') Overview:
A. Biosynthesis of methionine
(see also the Amino Acid Metabolism handout)

\[
\begin{align*}
\text{homocysteine} & \quad \xrightarrow{\text{N}^5\text{-methyl THF}} \quad \text{methionine} \\
\end{align*}
\]

B. Re-utilization of folates:

\[
\begin{align*}
\text{Tetrahydrofolate} & \quad \xrightarrow{\text{Carbon donor (e.g. serine or glycine)}} \quad \text{N}^5, \text{N}^{10} \text{methylene tetrahydrofolate} \\
\text{methionine} & \quad \xrightarrow{\text{NADH} + H^+} \quad \text{N}^5 \text{methyl tetrahydrofolate} \\
\text{homocysteine} & \quad \text{NAD}^+ \quad \text{Adeine} \\
\end{align*}
\]

C. Synthesis of S-Adenosyl Methionine

\[
\begin{align*}
\text{methionine} & \quad \xrightarrow{\text{ATP}} \quad \text{S-adenosyl methionine} \\
\end{align*}
\]

D. Uses of SAM - biological methylator
Example: Conversion of norepinephrine to epinephrine:

![Chemical Reaction Diagram]

Others: Conversion of phosphatidylethanolamine to phosphatidylcholine, methylation of mRNA and DNA

**E. AdoMet cycle**

![AdoMet Cycle Diagram]

**III. Pathologies:**
A. Folate deficiency is common. symptoms: megaloblastic anemia
weakness, anemia, anorexia
Appearance of large, immature erythrocytes ('megaloblasts') in the blood

B. several causes:

- dietary deficiency common
- alcoholism may compound folate deficiency
- inability to absorb folates (e.g. tropical sprue and non-tropical or celiac sprue)

Dietary folates are typically poly-glutamated (up to 6 \(\gamma\)-glutamyl residues)
We can absorb only the mono-glutamyl form
An enzyme 'conjugase' secreted by the brush border cells of the intestine
hydrolytically removes the extra glu residues so we can absorb the folate
Intestinal irritation can compromise production of conjugase

- possibly secondary to B12 deficiency: pernicious anemia

'Methyl trap' hypothesis and deficiency of vitamin B12:

B12 deficiency can be caused by autoimmune response to 'Intrinsic Factor', a
product of the gut that aids in the absorption of B12.
