2007-09

M1 - Cardiovascular / Respiratory, Fall 2007

Abrams, G.; Sisson, T.; Jacobson, P.

Diffusion of Gases

Thomas Sisson, M.D.
Objectives

• To understand the diffusion of gases in the lung
  – Define diffusion and contrast with bulk flow
  – State Fick’s law for diffusion
  – Distinguish between diffusion limitation and perfusion limitation
  – Describe the diffusion of oxygen from the alveoli into the blood
  – Describe the diffusion of CO₂ from blood to alveoli
  – Define diffusing capacity and discuss its measurement
Airway Branching

Bulk Flow vs. Diffusion

- The cross sectional area increases with airway generation.

- Large volume/time, with decreasing velocity at any point.
  - Imagine a fast flowing river reaching a delta.

- The velocity of gas during inspiration becomes tiny at the level of the respiratory bronchiole - at this level diffusion becomes the chief mode of gas movement.

Source: Undetermined
Gas Movement due to Diffusion

- Diffusion - movement of gas due to molecular motion, rather than flow.
  - Akin to the spread of a scent in a room, rather than wind.
  - Random motion leads to distribution of gas molecules in alveolus.
Gas Movement due to Diffusion

Diffusion

• Driven by concentration gradients:
  – differences in partial pressure of the individual gases.

• Movement of $O_2$ and $CO_2$ between the level of the respiratory bronchiole and that of the alveolar space depends only on diffusion.

• The distances are small, so diffusion here is fast.
Diffusion of Gas Through the Alveolar Wall

Alveolar airspace

Pathway of diffusion

  \[\text{Binds}\]
- Hemoglobin
Fick’s Law for Diffusion

\[ V_{\text{gas}} = \frac{A \times D \times (P_1 - P_2)}{T} \]

- \( V_{\text{gas}} \) = volume of gas diffusing through the tissue barrier per time, in ml/min
- \( A \) = surface area available for diffusion
- \( D \) = diffusion coefficient of the gas (diffusivity)
- \( T \) = thickness of the barrier
- \( P_1 - P_2 \) = partial pressure difference of the gas
Diffusivity

\[ D \approx \text{Solubility} / \sqrt{\text{MW}} \]

- \( \text{O}_2 \) has lower MW than \( \text{CO}_2 \)
- Solubility of \( \text{CO}_2 \) is 24x that of \( \text{O}_2 \)
- \( \text{CO}_2 \) diffuses 20x more rapidly through the alveolar capillary barrier than \( \text{O}_2 \)
Diffusion Across a Membrane

\[ \dot{V}_{gas} = \frac{A \cdot D(p_1 - p_2)}{T} \]

\[ D \propto \frac{\text{Solubility}}{\sqrt{MW}} \]

A = Area

P_1

P_2

T = Thickness
Limitations of Gas Transfer

- **Diffusion Coefficient.**
  - Different gases behave differently.

- **Surface Area and Thickness** of the alveolar wall.

- **Partial Pressure Gradient** across the alveolar wall for each individual gas.
  - Depends on both alveolar and mixed venous partial pressure (start of capillary).
Change in Blood Partial Pressure of Three Gases with Time in the Capillary

N₂O is Perfusion Limited

- N₂O is very soluble in biological tissues and diffuses rapidly.
- Pcn₂O rises rapidly in the alveolar capillary.
- Quickly have \( Pcn_2O = P_{AN_2O} \).
- Because there is no pressure gradient, no diffusion occurs after about 0.1 sec.
- Fresh blood entering the capillary has not yet equilibrated and can still take up N₂O.
- Increased blood flow will increase gas transfer.
- Transfer of N₂O is perfusion limited.
Change in Blood Partial Pressure of Three Gases with Time in the Capillary

Carbon Monoxide is **Diffusion Limited**

- Blood PCO rises very slowly because CO is bound to Hgb, with very little dissolved.
- Capillary PcCO does not approach $P_{A\text{CO}}$.
- Partial pressure gradient is maintained throughout the time the blood is in the capillary.
  - Diffusion continues throughout this time.
- Transfer of CO is limited by diffusivity, surface area, and thickness of the wall.
Transfer of Oxygen

Transfer of Oxygen

• Under normal conditions, $PcO_2$ reaches $PAO_2$ about 1/3 of the distance through the capillary.

• Therefore under normal conditions transfer is perfusion limited.

• With exercise, the time blood spends in the capillary is reduced- no longer perfusion but diffusion limitation.

• In the setting of thickened alveolar wall, transfer is reduced.
  – With severely disturbed diffusion, there is limitation even at rest
Transfer of Oxygen is Limited at Low Alveolar $O_2$
Transfer of CO$_2$

- Is transfer of CO$_2$ diffusion or perfusion limited?

The diagram illustrates the effects of varying alveolar oxygen pressure (P$_{O_2}$) and carbon dioxide pressure (P$_{CO_2}$) on the partial pressure of oxygen and carbon dioxide in the blood. The graphs show the changes in partial pressure over time as blood enters and leaves the capillary.

- **Alveolar P$_{O_2}$**:
  - Normal
  - $\frac{1}{4}$ Normal
  - $\frac{1}{8}$ Normal

- **Carbon dioxide partial pressure in blood (mm Hg)**
  - Mixed venous P$_{CO_2}$
  - Normal
  - $\frac{1}{4}$ Normal

- **Time in capillary (s)**

Transfer of CO$_2$

Why is the transfer of CO$_2$ so similar to that of O$_2$?

\[ V_{\text{gas}} = \frac{A \times D \times (P_1 - P_2)}{T} \]

Diffusivity of CO$_2$ is 20x > than that of O$_2$

Partial pressure gradient of CO$_2$ is 45→40

Partial pressure gradient of O$_2$ is 100→40
Fick’s Law for Diffusion

\[ V_{gas} = \frac{(AxD)}{T} x (P_1 - P_2) \]

- \( V_{gas} \) = volume of gas diffusing through the tissue barrier per time, in ml/min
- \( A \) = surface area available for diffusion
- \( D \) = diffusion coefficient of the gas (diffusivity)
- \( T \) = thickness of the barrier
- \( P_1 - P_2 \) = partial pressure difference of the gas

\( (AxD)/T = \text{diffusing capacity of the lung (DL)} \)
Diffusing Capacity

\[
\frac{(AxD)}{T} = \frac{\dot{V}_{\text{gas}}}{(P_{1x} - P_{2x})} = D_{Lx}
\]

Source: Undetermined
Measuring Diffusing Capacity

- Inhale mixture containing known concentration of tracer gas.
- Allow diffusion from alveolus into blood.
- Measure concentration of tracer in exhaled gas.
- Calculate rate of removal of tracer gas by diffusion into blood and the partial pressure gradient from alveolus into blood.

Choice of gas:
- Readily available.
- Easily measured.
- Diffusion limited.
- No arterial partial pressure.
We Could Use DLO$_2$

\[
\frac{\text{Ax} \times \text{D}}{\text{T}} = \text{DLO}_2
\]

\[
\dot{V}_{O_2} = \text{DLO}_2 \left( P_A O_2 - P_C O_2 \right) = \text{ml O}_2 / \text{min}
\]
Carbon Monoxide is an Ideal Gas for Measuring Diffusing Capacity

- CO binds avidly to hemoglobin.
- While CO content of the blood rises, the PCO in blood rises very slowly.
- The gradient of partial pressures from alveolus to blood remains almost constant during test.

Normal DLCO = 20-30 ml/min/mmHg
DLCO Has Two Components

Diffusion across the alveolar membrane.

Reaction with hemoglobin.

\[
\frac{1}{DL} = \frac{1}{Dm} + \frac{1}{\theta x Vc}
\]
Conditions that Impact Diffusion Capacity for CO.

\[ DLCO = \frac{AxD}{T} \]

- Decreased Surface Area.
  - Destruction of Alveolar Wall
- Increased Barrier Thickness.
- Anemia.
How would the Following Change the Diffusion Capacity of the Lungs?

- Changing from supine to upright
- Exercise
- Anemia
- Valsalva maneuver
- Low cardiac output due to hemorrhage
- Emphysema
- Pulmonary fibrosis
