M1 - Cardiovascular / Respiratory, Fall 2007

Abrams, G.; Sisson, T.; Jacobson, P.

Ventilation/Perfusion Matching

Thomas H. Sisson, M.D.
Objectives

• To recognize the importance of matching ventilation and perfusion
  – To explain the consequences of mismatched ventilation and perfusion
  – To define shunt and dead space physiology
  – To be able to determine the alveolar $pO_2$
  – To be able to determine the A-a $O_2$ gradient and understand the implications of an increased gradient
  – To explain and understand the consequences of regional differences in ventilation and perfusion due to effects of gravity
Ventilation and Perfusion at the Level of the Whole Lung

- Tidal Volume: 500 mL
- Anatomic Dead Space: 150 mL
- Alveolar Gas Volume: 3000 mL
- Volume of Blood in Pulmonary Capillaries: 70 mL
- Respiratory Rate: 15/min
- Total Ventilation: 7500 mL/min
- Alveolar Ventilation: 5250 mL/min
- Pulmonary Blood Flow: 5000 mL/min
- Ventilation/Perfusion: $\frac{V}{Q} = 1$

Gas Composition in the Alveolar Space

Trachea: partial pressure of CO2 is approximately 0

\[ \text{PiO}_2 = (\text{barometric pressure} - \text{H}_2\text{O vapor pressure}) \times \text{FiO}_2 \]
\[ = (760 - 47) \times 0.21 = 150 \text{ mmHg} \]

In the alveolar space, oxygen diffuses into the blood and CO2 diffuses into the alveolus from the blood.
Alveolar Gas Equation

\[ PAO_2 = (PiO_2) - (PaCO_2/R). \]

PaCO\(_2\) approximates PACO\(_2\) due to the rapid diffusion of CO\(_2\)

\[ R = \text{Respiratory Quotient (VCO2/V02)} = 0.8 \]

In a normal individual breathing room air:

\[ PAO_2 = 150 - 40/0.8 = 100 \text{ mmHg} \]
Gas Composition in the Normal Alveolar Space

Trachea: partial pressure of CO2 is approximately 0

\[ \text{PiO}_2 = (\text{barometric pressure} - \text{H}_2\text{O vapor pressure}) \times \text{FiO}_2 \]
\[ = (760 - 47) \times 0.21 = 150 \text{ mmHg} \]

In the alveolar space, oxygen diffuses into the blood and CO2 diffuses into the alveolus from the blood.
Consequences of Inadequate Ventilation

• Apnea:
  – PACO2 rises
  – PAO2 falls until there is no gradient for diffusion into the blood

• Hypoventilation:
  – Inadequate ventilation for perfusion
  – PACO2 rises
  – PAO2 falls, but diffusion continues
How Can We Tell if Alveolar Ventilation is Adequate?
PaCO2 and Alveolar Ventilation

• PaCO2 is:
  – directly related to CO2 production (tissue metabolism).
  – Inversely related to alveolar ventilation.

• Increased PaCO2 (hypercarbia) is always a reflection of inadequate alveolar ventilation (VA).

\[ \text{PaCO2} \approx \frac{V_{CO2}}{VA} \]
Suppose a patient hypoventilates, so that the PCO2 rises to 80 mmHg. We can estimate the PAO2 based on the alveolar gas equation.

\[
\text{PAO2} = 150 - \frac{80}{0.8} = 50 \text{ mmHg}
\]

Thus even with perfectly efficient lungs, the PaO2 would be 50, and the patient would be severely hypoxemic. Therefore, hypoventilation results in hypoxemia.
V/Q Matching

• 300 million alveoli.

• Different alveoli may have widely differing amounts of ventilation and of perfusion.

• Key for normal gas exchange is to have matching of ventilation and perfusion for each alveolar unit
  – Alveoli with increased perfusion also have increased ventilation
  – Alveoli with decreased perfusion also have decreased ventilation
  – V/Q ratio = 1.0
Two Lungs, Not One

• Suppose the left lung is ventilated but not perfused (dead space).

• Suppose the right lung is perfused but not ventilated (shunt).

• Total $V/Q = 1$, but there is no gas exchange ($V/Q$ must be matched at level of alveolar unit).
One lung unit has normal ventilation and perfusion, while the other has inadequate ventilation.

- Normal ventilation and perfusion:
  - PO2 114

- Low ventilation and perfusion:
  - PCO2 ↑
  - PO2 ↓
  - PO2 50
  - PO2 ?
What is the PO2 of a mixture of two volumes of blood with different initial PO2?

Determined by interaction of oxygen with hemoglobin.

- the partition of oxygen between plasma (and thus the pO2) and bound to hemoglobin is determined by the oxyhemoglobin dissociation curve.
Oxyhemoglobin Dissociation Curve

\[ CO_2 = (1.3 \times HGB \times Sat) + (.003 \times PO_2) \]

- Oxygen Combined With Hemoglobin
- Dissolved Oxygen

- % Hemoglobin Saturation
- Oxygen Content (ml/100 ml)
- \( P_{O_2} \) mmHg
Low V/Q Effect on Oxygenation

One lung unit has normal ventilation and perfusion, while the other has inadequate ventilation.

- PO2 114 (Normal)
- PO2 50 (Low V/Q)
- PO2 114 (Normal)
- PO2 ? (Low V/Q)

↑ PCO2
↓ PO2
Oxyhemoglobin Dissociation Curve and O2 Content

- **Total Oxygen**
- **Oxygen Combined With Hemoglobin**

**Graph Details**:
- **% Hemoglobin Saturation** vs. **P_{O_2} mmHg**
- **Oxygen Content (ml/100 ml)** vs. **Oxyhemoglobin**

- **P_{O_2}** values range from 0 to 100 mmHg.
- **% Hemoglobin Saturation** values range from 0 to 100.
- **Oxygen Content (ml/100 ml)** values range from 0 to 20.

The graph illustrates the relationship between oxygen saturation and partial pressure of oxygen in the blood, highlighting the dissociation curve and oxygen content.
Low V/Q Effect on Oxygenation

One lung unit has normal ventilation and perfusion, while the other has inadequate ventilation.

Normal:
- PO2 114 mmHg
- O2sat 100%
- O2 content 20ml/dl

Low V/Q:
- PO2 50 mmHg
- O2sat 80%
- O2 content 16ml/dl

Oxygen Combined With Hemoglobin
Low V/Q Effect on Oxygenation

One lung unit has normal ventilation and perfusion, while the other has inadequate ventilation.

- Normal: PO2 114 mmHg, O2sat 100%, O2 content 20ml/dl
- Low V/Q: PO2 50 mmHg, O2sat 80%, O2 content 16ml/dl
- PO2 60mmHg
PCO2 in V/Q Mismatch

- Increased ventilation can compensate for low V/Q units.
  - Shape of CO2 curve
- Total ventilation (VE) must increase for this compensation.
Extremes of V/Q Inequality

- **Shunt**
  - Perfusion of lung units without ventilation
    - Unoxygenated blood enters the systemic circulation
    - $V/Q = 0$

- **Dead space**
  - Ventilation of lung units without perfusion
    - Gas enters and leaves lung units without contacting blood
    - Wasted ventilation
    - $V/Q$ is infinite
Effect of Changing V/Q Ratio on Alveolar PO2 and PCO2

Picture showing the effect of changing the V/Q ratio on alveolar PO2 and PCO2. The diagram illustrates the gas composition and V/Q ratio for different scenarios:

- **Shunt**
  - $P_{O_2} = 40\text{mmHg}$
  - $P_{CO_2} = 45\text{mmHg}$

- **Dead Space**
  - $P_{O_2} = 150\text{mmHg}$
  - $P_{CO_2} = 0\text{mmHg}$

**Gas Composition**
- Mixed Venous Blood
- Normal
- Inspired Air

**V/Q**
- 0
- 1
- $\infty$
Effects of V/Q Relationships on Alveolar PO2 and PCO2
Shunt Physiology

One lung unit has normal ventilation and perfusion, while the
has no ventilation

Normal

Shunt

PO2 114 mmHg
O2sat 100%

PO2 114 mmHg
O2sat 100%

PO2 40 mmHg
O2sat 50%

PO2 40 mmHg
O2sat 50%

PO2 49 mmHg
O2sat 75%
Response to Breathing 100% Oxygen

- Alveolar hypoventilation or V/Q mismatch responds to 100% oxygen breathing.
- Nitrogen will be washed out of low ventilation lung units over time.
- PaO2 will rise to > 550 mmHg.
- Limited response to oxygen in shunt.
- Use this characteristic to diagnose shunt.
Shunt Calculation

• $Qt \times CaO2 = \text{total volume of oxygen per time entering systemic arteries}$
  - $Qt = \text{total perfusion}$
  - $Qs = \text{shunt perfusion}$
  - $CaO2, Cc’O2, CvO2$ are oxygen contents of arterial, capillary and venous blood

• $(Qt - Qs) \times Cc’O2 = \text{oxygen coming from normally functioning lung units}$

• $Qs \times CvO2 = \text{oxygen coming from shunt blood flow}$
Shunt

\[ \dot{Q}_t, C_{\bar{v}O_2}, \dot{Q}_s, C_{c'O_2}, C_{aO_2}, \dot{Q}_t \]
Shunt Equation

\[ Qt \times CaO2 = [(Qt - Qs) \times CcO2] + [Qs \times CvO2] \]

\[
\frac{Qs}{Qt} = \frac{Cc'O2 - CaO2}{Cc'O2 - CvO2}
\]
Causes of Shunt

• Physiologic shunts:
  – Bronchial veins, pleural veins

• Pathologic shunts:
  – Intracardiac
  – Intrapulmonary
    • Vascular malformations
    • Unventilated or collapsed alveoli
Detecting V/Q Mismatching and Shunt

• Radiotracer assessments of regional ventilation and perfusion.

• Multiple inert gas elimination.
  – Takes advantage of the fact that rate of elimination of a gas at any given V/Q ratio varies with its solubility.

• A-aO2 Gradient.
V/Q Relationships

Multiple Inert Gas Elimination

A-a O2 gradient

- In a totally efficient lung unit with matched V/Q, alveolar and capillary PO2 would be equal.

- Admixture of venous blood (or of blood from low V/Q lung units) will decrease the arterial PaO2, without effecting alveolar O2 (PAO2).

- Calculate the PAO2 using the alveolar gas equation, then subtract the arterial PaO2: \[(PiO_2) - (PaCO_2/R)] - PaO2.

- The A-a O2 gradient (or difference) is < 10-15 mmHg in normal subjects
  - Why is it not 0?
Apical and Basilar Alveoli in the Upright Posture

- Elastic recoil of the individual alveoli is similar throughout the normal lung.

- At end expiration (FRC) apical alveoli see more negative pressure and are larger than basilar alveoli.

- During inspiration, basilar alveoli undergo larger volume increase than apical alveoli.

- Thus at rest there is more ventilation at the base than the apex.

- Also More Perfusion to Lung Bases Due to Gravity.
Effects of Gravity on Ventilation and Perfusion

Effects of Gravity on Ventilation and Perfusion Matching

Causes of Abnormal Oxygenation

• Hypoventilation
• V/Q mismatch
• Shunt
• Diffusion block
Key Concepts:

- Ventilation and Perfusion must be matched at the alveolar capillary level.

- V/Q ratios close to 1.0 result in alveolar PO2 close to 100 mmHg and PCO2 close to 40 mmHg.

- V/Q greater than 1.0 increase PO2 and Decrease PCO2. V/Q less than 1.0 decrease PO2 and increase PCO2.

- Shunt and Dead Space are Extremes of V/Q mismatching.

- A-a Gradient of 10-15 Results from gravitational effects on V/Q and Physiologic Shunt.
