16. Abstract A total of 87 traditional and functional body measurements were taken on a sample of 4127 infants, children and youths representing the U.S. population aged 2 weeks through 18 years. Measurements were taken throughout the United States by two teams of anthropometrists using an automated anthropometric data acquisition system. Standard anthropometers, calipers, and tape devices were modified to read electronically and input dimensional data directly to a mini-computer for data processing and storage. Summary statistics of measurement results are reported for 16 age groups along with scatter plots of the data points for the sexes combined and males and females separately. Each measurement is described along with a photograph and illustration. In addition bivariate relationships of selected functional measurements with weight or stature are provided along with regression data.

ACKNOWLEDGMENTS

The authors wish to gratefully acknowledge the cooperation and assistance provided in this multidisciplinary effort by a large number of dedicated individuals over the 22-month period of this study. The measurement teams, comprised of Terri Gendel, Susan Kornfield, Elaine Caplan, Robert Kay, and Robert Prince deserve particular credit for conscientiously and cheerfully taking the measurements on 4127 subjects often under difficult conditions. Elizabeth Read provided coordination of schedules for the teams with the participating schools and teachers, as well as back-up measurement assistance. We are indebted to Leigh Peck for the design, fabrication, and maintenance of much of the mechanical, electrical, and computer hardware; to Elaine Umholtz for the illustrations and artwork; to Kathleen Jackson for the cover illustration; and to Carol Ann Birch, who typed the manuscript and maintained the records. A special thanks also to Kurt Metzger who provided the programs and equipment for copying Linc tapes to DEC tapes for transfer of data to the Michigan Terminal System, and to James Freeman who was primarily responsible for implementation of the editing programs on the HSRI PDP 11/45 computer system.

Professional contributions and assistance were provided by a number of individuals. Dr. Larry Roi, Biostatistical Department of the University of Michigan, gave generously of his time in assisting with selection of alternate site locations. Dr. Guy Rieff, Professor of Physical Education, University of Michigan, provided us the use of his sampling frame for selecting our measurement locations. The X-VAL editing program was provided by Mr. Charles E. Clauser, Crew Systems Integration Division, Wright-Patterson Air Force Base. Valuable advice was also contributed by Joseph W. Young, Physical Anthropologist, Civil Aeromedical Institute, Federal Aviation Administration, U. S. Department of Transportation, Oklahoma City, and by Dr. John McConville, Webb Associates, Yellow Springs, Ohio.

The foresight and guidance of the project officers who have

managed this program, Dr. Albert F. Esch and Technical Monitor Donald T. Van Houten, deserve special recognition due to their major contribution to the overall conduct of the work. This effort is the culmination of earlier studies initiated by Carl W. Blechschmidt (April 1972-November 1973), and subsequently under the technical guidance of John K. O'Connor (November 1973-April 1974). Elaine Besson, formerly of the National Commission on Product Safety, provided early encouragement.

The authors also wish to express appreciation to the approximately 468 school, day care center, nursery, child care center and baby clinic administrators, teachers, physicians, and nurses who willingly gave their time and generous cooperation.

And finally, we wish to acknowledge the 4127 infants, children and youth, and their parents throughout the country without whose willing participation this study could not have been conducted.

CHAPTER I

INTRODUCTION

A. Introduction

In 1975, the Biomedical Department of the Highway Safety Research Institute (HSRI) under the sponsorship of the Consumer Product Safety Commission (CPSC) completed an anthropometric survey of infants and children to age 12 (22). In that study, 41 measurements chosen for their functional application to design of children's products were obtained on a sample of over 4000 infants and children representative of the current U.S. population. The present study is a continuation and extension of this survey and is an attempt to provide a more complete source of useful anthropometric data on children and youths through age 18. In this continuation study, data on 87 measurements have been obtained on over 4100 additional subjects two weeks through 18 years of age, representing as nearly as possible the U. S. population with regard to race, demographic, and socio-economic factors. This report describes the procedures and presents the results of this study.

Chapter I contains two additional sections. Section B provides a brief description of related anthropometric background material and Section C presents the overall investigation objectives.

Chapter II discusses the methods and procedures including the measurement and sampling strategy designed to provide a maximum amount of data on a sample representative of the United States Youth 0-18 years of age. In addition, a complete description of the measurement equipment is included.

The main body of the report is found in Chapter III which is divided

This study was annually reviewed by, and conducted under standards established by the University of Michigan Medical Center, Committee to review Grants for Clinical Research and Investigation Involving Human Beings, and conforms to the guidelines of the Institutional Guide to Department of Health, Education and Welfare Policy on Protection of Human Subjects.

into six sections of results. Section A describes the final sample by sex, age, race and geographical location. Section B contains the measurement results for 2-18 year olds. Each measurement is presented separately along with a measurement description, photograph, illustration, and results. These results are presented using both tables of summary statistics by age group (one year intervals) and scatter plots of the actual data points versus age for combined sexes, and males and females separately. In Section C the tabular results for 2-18 year olds are presented in measurement groups according to body region with one age group per table. In Section D the relationships between selected functional measurements and height and weight are described using bivariate scatter plots and tables of regression and correlation coefficients. In Section E the results for infants are presented using tabular and graphical presentations along with measurement descriptions, photographs, and illustrations, while Section F is a glossary of anatomical and anthropometric terms used in the measurement descriptions.

Chapter IV contains a brief discussion of these results.

B. Related Background

According to figures from the National Center for Health Statistics, Health Services, and Mental Health Administration, U.S. Department of Health, Education and Welfare, over 52,000 infants under one year of age and over 24,000 children from one to fourteen years died in 1974 (9). While the majority of infant fatalities each year are due primarily to endogenous factors during the first four post-natal weeks, the deaths are increasingly due to exogenous environmental influences from four weeks on (1). After age one year, accidents were the leading cause of childhood deaths (5,6,10,24), accounting for 4,300 of the 11,548 reported deaths in the one- to four-year age group (9).

Regarding injuries, recent data (1975) from the Consumer Product Safety Commission indicate that more than 2 million children are in-

jured each year in accidents involving toys, playground equipment, bicycles, and other children's and household products(15). It has also been estimated in testimony by the U. S. Department of Health, Education and Welfare (22) that toys alone are responsible for injuries to 700,000 children each year and that from 403,000 (2) to 760,000 (14) children require medical attention each year from bicycle accidents.

Needless to say, a large number of these injuries and deaths are due to causes beyond the control of the product designer. Yet, while most accident reporting procedures of the past have used generalized categories and vague terminologies to classify causes of injuries and deaths in accidents, evidence is mounting to suggest that a large number of accidents to infants and children are a result of poorly or improperly designed commercial products. For example, communications with individual pediatricians and coroners support the fact that many cases of death and injury to infants have resulted from improper or dangerous design of infant or juvenile furniture.

While there are many reasons why a toy or household product may be physically unsafe (e.g., sharp edges, points and protrusions, faulty mechanisms, etc.), a primary factor which has general application to almost all products is concerned with the physical dimensions and features of the product and its components as they relate to the physical characteristics of the user or other individuals who may come in contact with the product. For example, how large or small should holes and spacings in toys, furniture slats, railings, and appliance ventilation covers be so that infants and children do not get their heads, fingers, and hands stuck or injured? How should strollers, high chairs and tricycles be designed to prevent accidents due to instability? Or, what should be the dimensions of bicycles and bicycle hand brakes, school desks, school bus seats, playground equipment, etc. designed for use by children of specific ages and/or body sizes? Answers to these and many other questions require that

a complete and reliable source of the physical characteristics of infants, children, and youth be available to designers, engineers, and other groups concerned with establishing guidelines and standards for the manufacture of these products. As of 1972, however, such a source of reliable and consistent data providing measurement statistics for both traditional and functional anthropometric measures for a sample representative of the infants, children, and youth in the United States was not available.

In 1972 the Biomedical Department of the University of Michigan's Highway Safety Research Institute completed a literature survey of anthropometric studies of infant and child measurements. The results, which constitute a comprehensive review of child and infant measurements, are presented in Source Data of Infant and Child Measurement: Interim Data 1972 (18) which references over 800 studies providing child measurement data.¹ While this comprehensive review of the literature on child and infant anthropometry data revealed that a large number of studies had been conducted, the data urgently needed for a number of current safety applications were non-existent. A large number of these studies were longitudinal (rather than cross-sectional) surveys designed to study the growth of a fixed population over a period of time using only a few basic measures such as height and weight. All the studies were limited in that they either used specific populations, selected age ranges, or only a few measurements, and did not consider differences due to region of the country, race, and other environmental and socio-economic factors likely to affect the sizes of children. Even if these factors had been considered and if all the measurements necessary had been taken in one study or another, differences due to measurer technique, definitions in measurements, and differences in age groupings would make it impossible to compile these data into one common source of reliable and consistent information. Additionally, many growth studies as recently as Marshall and Carter, 1975 (7)

¹ See reference 22 for a brief discussion of these studies.

have found that children today are taller and larger than children their same age in past generations. Since only one-third of the 35 most complete studies encountered had been made since 1960, it is questionable how representative much of these data may be of the current population of U. S. children.

In 1972, as a result of the clear need for more useful and current child measurement data for product safety design, the Consumer Product Safety Commission contracted with the University of Michigan to undertake the task of providing these data. The study which resulted was completed in March, 1975 and the data were reported in the publication Physical Characteristics of Children as Related to Death and Injury for Consumer Product Safety Design (22). A total of 41 body measurements were taken on over 4,000 infants and children representing the U.S. population from 2 weeks through 12 years of age. An important aspect of this study was the design, fabrication, and use of a portable mini-computer system for automatic retrieval of measurement data. Standard anthropometers, calipers, and tape devices were modified to output electrical signals to the computer and pressure transducers were utilized to standardize measurements on soft tissue. Devices were also designed for fast and reliable measurements of whole-body centers of gravity in the standing and seated positions and for obtaining a number of functional measurements such as hand clearance, grip size, and finger diameters.

C. Objectives

The overall objective of the present study was to provide a complete source of anthropometric data on U. S. children for consumer product(s) design, hazard assessment and guidance in establishing requirements or recommendations in standards. In carrying out a study of this complexity, it was necessary to subdivide the effort into the following tasks.

1. Develop a list of traditional and functional anthropometric measurements most urgently

needed on infants, children and youth from 2 weeks to 18 years for broad application to product safety design.

2. Determine a measurement strategy and sampling procedure that would efficiently and accurately collect these data on a sample representative of the total U. S. population of infants, children, and youth.
3. Make necessary modifications to existing anthropometric instruments and assemble a second portable computer system for collecting these anthropometric data.
4. Collect, reduce, and analyze the required dimensional data.
5. Tabulate and present the data in a format or formats most useful to persons concerned with designing or establishing guidelines and standards for children's products, taking into consideration the potential functional applications.

CHAPTER II

METHODS AND PROCEDURES

A. Study Design

As stated in the objectives, the purpose of this study was to provide anthropometric data of both a functional and traditional nature to describe the sizes of infants, children and youths from 0 to 18 years. In order that the study sample represent as closely as possible the children and youth of the 48 conterminous United States, the cooperation and consultation of the University of Michigan Biostatistics Department was obtained. From an extant list of public schools available from the third round (1975) of a study of youth fitness completed in the Department of Physical Education at the University of Michigan, a sub-sample was selected for this study.

The selection procedure used in the Youth Fitness Study is described in detail in Reiff, Kish and Harter (16). In brief, the Survey Research Center, University of Michigan, maintains economic, demographic, and sociological information on a national sample representative of the United States population consisting of 74 primary sampling units (PSU's) which are made up of one or more counties. These PSU's include the 12 largest standard metropolitan statistical areas (SMSA's) plus 62 other PSU's which are divided into two groups both representative of the population outside the 12 largest SMSA's. The sampling frame utilized in the Youth Fitness Study was selected from the 12 SMSA's in one of these halves, and consisted at the first stage of the 12 largest central cities, 22 suburban counties selected from these 12 SMSA's and the 31 counties outside the 12 SMSA's.

In the Anthropometric Study of this report, 8 of the 12 cities were randomly selected and 10 counties neighboring the chosen 8 cities and 15 of the remaining 31 counties were then obtained

by a random process. Within each of the chosen areas one school district was randomly selected.

Next, within each district a level or levels of schools [elementary school (usually K-6), intermediate school (usually 7-9) and high school (usually 10-12)] were selected. Schools were selected randomly from among those with a given grade range and grade levels were selected randomly so that the resulting sample was balanced in the ratio 2 elementary to 1 intermediate to 1 high school.

Unfortunately, selection of a school district or school by this sampling scheme did not guarantee its participation in the study. Refusals of school boards, school superintendents, or principals, and practical limitations of school buildings such as space available made it necessary to select alternative districts or schools as scheduling progressed. Thus, the ideal of adhering rigidly to the original sampling scheme could not be realized and it was imperative to remain flexible. In each case where substitutions were necessary, however, every effort was made to make the substitution from the same city, county or geographic area. It should be noted that the Ann Arbor Area was included in addition to sampling dictated by the National Sampling Scheme.

B. Measurements and Measurement Strategy

1. General

Traditionally, anthropometric measurements have been devised solely to describe human variation in body morphology, body proportions, and changes in size attributed to growth, race, and other variables of interest to anthropologists. These dimensions were taken to describe the linear distance between two landmarks (heights, breadths and depths) or around a body segment at a prescribed level (circumference). In today's world, however, this classical approach to anthropometry is not sufficient to answer questions relevant to the interaction of man with a multitude of man-made environments.

While the traditional anthropometry measures are still important as they describe differences between individuals and populations, the differences must also be considered as a part of a "man-machine system". Thus, in anthropometric studies today, functional measurements which describe physical characteristics in relation to man's performance in his environment must be considered as well as the more traditional type measurements.

2. Ages 2-18 Years

With a systems approach to anthropometry as a general guiding principle and with the recognition of the need for a complete and consistent data bank of both classical and functional anthropometry on U. S. children and youth for application to product design, the process of selecting measurements for this study was initiated. Consideration was also given to the fact that another study of this magnitude would not be likely in the near future and it was thus essential to provide the maximum amount of information possible within the time and budget limitations and to identify those measurements that would be of most interest and usefulness to the greatest number of people (e.g., safety engineers, medical doctors, human factors specialists and others).

The result of these considerations was the list of 87 functional and traditional measurements shown in Figure 1. Traditionally, all measurements in anthropometric surveys are made on every subject in the survey sample. It was realized at the outset, however, that neither the children or the schools would permit the time for 87 measurements on each subject. Previous experience had indicated that 15-20 minutes is a maximum time interval for both of these factors, which allows about 40 measurements to be taken. Thus, an alternative measurement strategy was needed.

In essence, this new strategy divides the measurements into four groups as indicated in Figure 1. One group of 22 measurements (Group I), called core measurements, was taken on every subject. The

I. Core Measurements

other three groups of measurements called body shape (Group II), linkage and center-of-gravity (Group III), and head, face and hands (Group IV) were taken sequentially along with the core measurements on every three subjects. Thus, on any one subject only 42-45 measurements were taken. While the sample size for the core measurements is equal to the total number of subjects in the study, for the other three data sets the sample size is only one third the total sample size.

The key factor in this approach is in the choice of the core measurements which have been carefully selected to include measurements highly correlated with each of the measurements in the other three data sets. Since the core measurements are taken on every subject and each of the other measurements is correlated with one or more of the core measurements, comparison of the core measurements associated with the three other measurement groups provides a procedure for checking the comparability and representativeness of the sample for the separate measurement sets.

In order to avoid the systematic association of measurements with subjects for a particular region of the country or age group, all measurement sets were taken equally at all measurement sites. To accomplish this, the combination of measurement sets (core + shape, core + linkage, core + head, face and hands) was sequenced in the computer program.

In summary, then, the measurements in this study were selected to provide maximum information for the maximum number of potential users. This was accomplished by a new measurement strategy which takes advantage of the strong relationships between certain anthropometric measurements, thereby permitting a large number of measurements to be taken on a large cross-sectional sample with a minimum amount of time per subject.

3. Infants (0-24 months)

Since infants are not capable of performing most of the

functional measures and do not have mature skeletal and muscular systems, many of the measurements taken on 2-18 year olds cannot be taken on infants. For this reason, a separate list of 34 measurements was compiled for infants and is illustrated in Figure 2.

C. Data Collection Procedures

1. Measurement Teams

Measurements were taken by two teams of anthropometrists, one consisting of two females, the other of two males. Each team member was chosen primarily on the basis of experience in working with children and teenagers. During the initial phase of the study the measurers underwent an extensive training period in skeletal anatomy and anthropometry techniques. Prior to conducting any field measuring the teams underwent one month of closely-supervised practice measuring at HSRI so that they were comparable in how they handled the equipment and took the measurements. A fifth team member had primary responsibility for coordinating and scheduling measurement locations but was also trained along with the measurement teams to take all measurements and

could be used as a substitute in the absence of a team member.

2. Measurement Site Scheduling

a. Public Schools. Most measuring was conducted within the U. S. public school system in accordance with the sampling scheme discussed previously. The scheduling process generally involved contacting the superintendent of a chosen school system by letter, and a week or so later following up with a telephone call. Information concerning the purpose and procedures of the project, along with estimates of the number of students needed and expected length of stay in the school district, were then sent out and the project was brought before the school board for consideration. If approved, the names and addresses of selected elementary, secondary, and high schools in the district were obtained and individual principals contacted. In many cases, the team coordinator visited the chosen schools and made a presentation of the study to the teachers and students. In this regard, an 18 minute color movie produced in the previous CPSC measurement study was an invaluable aid. Often it was sufficient to send the movie alone to a particular school in order to describe the study to students and teachers.

In general, if the study was approved by the school board and superintendent, the individual principals were usually willing to allow the study to be conducted in their school. While every attempt was made to adhere to those schools chosen by the statistical sampling scheme, this was not always possible due to inadequate space, physical layout of the building (i.e., could the computer be easily moved in and out of the school), and the coordination of our measuring schedule with school activities (e.g., exams, holiday programs, etc.).

Once it had been decided that a school would be used in the study, the forms and letters illustrated in Figures 3, 4, and 5 were distributed to the students. These consist of a letter of explanation to the parents, a consent form and a questionnaire of demographic information about the child and child's family. Since it would be

HIGHWAY SAFETY RESEARCH INSTITUTE
 Institute of Science and Technology
 Huron Parkway and Baxter Road
 Ann Arbor, Michigan 48109

THE UNIVERSITY OF MICHIGAN

Dear Parent:

The Highway Safety Research Institute and the Department of Pediatrics of the School of Medicine at The University of Michigan are jointly conducting a study of infant, child, and teen-age body sizes. During the next year we plan to take measurements on over 3,600 youths throughout the United States from birth to 18 years, and we have recently made arrangements to measure in your school.

This research is being sponsored by the Consumer Product Safety Commission for the purpose of collecting measurement data which can be used as guidelines for design of safer consumer products. This would include such items as children's furniture, playground equipment, car seats and restraints, toys, bicycles, etc.

The measurements will be taken by two teams consisting of two experienced research assistants each. Measurements are taken with automated instruments designed especially for use with children and youths. Many find the equipment interesting, and the measurement experience enjoyable. Our protocol has been approved by the Human Subjects Committee of the University of Michigan Medical School.

The present study is a continuation and extension of an earlier three-year study which we concluded in March, 1975. At the completion of this study, information on over 90 body dimensions will be available to product designers. These results will have a number of direct and basic applications in improving consumer products and in forming a valid framework for governmental standards. As one example of the importance of these data, our measurements of 3- to 6-month old infants formed a basis for the government's recent issuance of safer crib standards, reducing slat interspaces from 3 1/2" to 2 3/8" to prevent the hazard of infants sliding between the slats.

We have included a brief questionnaire with this letter. Because our sample will reflect the total U.S. population of children, we need to ask questions about race, education, and occupation. This information is strictly confidential and will be released only in an anonymous form.

Thank you for your cooperation.

UNIVERSITY OF MICHIGAN MEASUREMENT STUDY

Consent Form

I, the undersigned, understand that the purpose of this study is to take some measurements on my son or daughter. I am aware that these measurements will enable us to acquire information about the physical shapes of youths at different ages and to use this information in constructing guidelines for the design of safer consumer products for youths.

I have been informed that there are no health hazards or discomfort to my son or daughter associated with this, and that participation is voluntary. In order to take measurements with accuracy, it is necessary for the subject to partially undress, leaving on his/her underwear or to wear a bathing suit (preferably two-piece for the girls). Each subject is measured individually by research investigators of the same sex and all steps are taken to insure privacy.

I further understand that these data are confidential and I agree to allow publication of any or all of the data collected on my child if presented in an anonymous form.

Figure 5. Subject Questionnaire Form

economically prohibitive to distribute forms to all students in all the schools visited, a plan for distributing the forms to certain classes covering the age ranges of interest was worked out with each school principal. In a few cases, the school principal included a letter of his own with this package, acknowledging his approval of the study and encouraging participation. If this was done, the student and parent responses were usually very favorable.

If a school board did not approve the project an alternative school district was selected via a sampling scheme developed by the University of Michigan Biostatistics Department or a district in close proximity to the original district was approached.

The complete process of obtaining approval, making preparations to measure in individual schools, and getting forms back from students and parents generally took about 2 months. Because of the possibility of unanticipated problems (e.g., flu epidemics, teacher strikes) it was also necessary to remain somewhat flexible in setting firm measurement dates with schools and to have alternative measuring sites available. Thus, considerable effort in planning and scheduling was needed in order that the measuring teams could continue from location to location in a smooth and coordinated manner.

b. Summer Schedule. Because public schools are closed for 2-3 months during the summer it was necessary to change the scheduling procedure somewhat during this period. Overnight summer camps were a logical alternative and efforts were directed toward scheduling and measuring at these facilities. While there was less difficulty in obtaining approval from camp directors to conduct the study, other problems created a less desirable situation for measuring than in the public schools. The physical facilities at camps were usually not as conducive to using the automated system, either due to stairs, inadequate space, or inadequate power. Also, since the parents are only at camp to bring their children, it was necessary to explain the project and get parental approval during the first day of camp. Despite these drawbacks, which resulted in a decrease in the

rate of measuring, camps were the primary source of subjects over 6 years old during the summer months.

c. Preschool Measuring. While 5 through 18 year olds were measured in public schools, the primary sources for children 2 through 5 years were nursery schools and day-care centers. As with the camps, it was generally easier and faster to obtain approval for measuring than in public schools. Because these preschool facilities generally have 50 or fewer children, it was often necessary to move and set up the equipment two or three times a week. Perhaps the greatest problem in measuring 2-5 year old children was due to the unwillingness of many of them to be measured. It was thus not infrequent that a nursery school would have a good response of parental consent, but fewer children could actually be measured.

d. Measuring at HSRI and Infant Clinics. Since 2-3 year olds were often unwilling to be measured and since there are relatively few 2-3 year olds in the preschool centers, an alternative source for these children was needed. One procedure which was found useful for infants and toddlers was to obtain names of children born on selected dates from newspapers at the local library. Parents were contacted by phone and asked if they would bring their child or infant to HSRI for measuring. While the process was tedious and time consuming, a number of subjects aged 2 weeks to 3½ years were obtained in this way. Two other primary sources for measuring infants were the University of Michigan Well Baby Clinic and a pediatrician's clinic in Pontiac, Michigan.

D. Measurement Equipment and Procedures

1. Computer Systems

The basic process of collecting anthropometric data was automated to a large extent by use of a portable computer system illustrated in Figure 6. This system includes the NOVA 1220 computer with 24 K of memory, two tape drive units, 16 channels of A/D input, a signal conditioning and power supply package for processing instru-

ment signals and activating device transducers, and an interactive display system consisting of terminal, keyboard and video display. Figure 7 shows a typical set-up of the automated measuring process. Since two teams operated independently and simultaneously, often in different locations, two automated systems were needed. One system had been developed in the previous CPSC child measurement study (22), while a second system was constructed early in the present study.

Figure 6. Computer System Used for Anthropometric Data Acquisition

2. Automated Anthropometric Devices

Four different automated measuring devices were interfaced with the NOVA computer system and utilized in the measuring process. For measuring linear distances (i.e., breadths, lengths, depths, heights) the automated calipers or anthropometer was used. These instruments are illustrated in the drawings of Figure 8 and have

been previously described (11-13, 20-22). GPM (Siber Hegner & Co. Ltd) anthropometers and calipers were modified to provide electrical

Figure 7. Typical Measuring Set-Up Using Automated Anthropometry System.

Figure 8. Drawings of Modified Calipers (left) and Anthropometer (right) Illustrating Potentiometer, Pulley and Cable System, Pressure Transducer and Switch.

readout of length by means of a 10-turn potentiometer connected to the moving blade by a pulley and cable system. A miniature pressure transducer (Konigsberg Model P21) mounted in the special plexiglass blade provided a means of standardizing measurements on soft tissue. Figure 9 shows the actual instruments along with sets of removable pointed extensions of varying length for taking body linkage and head, face and hand measurements. A button in the stationary blade is used to activate the measuring process on each device.

Figure 9. Modified Calipers (left) and Anthropometer (right) with Removable Pointed Blades and Anthropometer Extensions.

Figure 10 shows a third automated device used for measuring various body circumferences. This consists of a standard steel measuring tape wrapped around a pulley which is attached to the shaft of a 10-turn potentiometer. The tape is wrapped about the particular body segment being measured and clipped back on the tip of the aluminum tape guide. Tension is provided by a coil spring located inside the pulley and the measurement is sensed by the computer upon depressing the plastic button with the thumb or index finger.

A fourth device used to measure the center of gravity is illustrated in Figure 11. This device consists of a platform supported

by three precisely calibrated load cells. The subject is placed on the platform in either a supine standing or supine sitting position with the feet or buttocks firmly against a reference plane. Outputs of the load transducing cells are amplified before entering the A/D unit of the computer and during execution of the center of gravity measuring routine, load cell sampling is initiated by depressing a keyboard key. In order to eliminate error caused by subject movement, each transducer is sampled 1600 times in about a

Figure 10. Modified Tape Device

1-second time interval and the average A/D readings computed. Since the transducers have been precisely calibrated, the weight and location of the subject's center of gravity with respect to the reference plane can be calculated from load cell readings taken with and without the subject on the platform. By reading the load cells with the platform tilted 15 degrees to the horizontal as shown in Figure 12, one can in theory compute the location of the subject's center of gravity above the platform as well as along the platform. In practice, however, small measurement errors introduced in measuring the center of gravity between the load cells become magnified in computing the center of gravity above the platform and make field measure-

Figure 11. Center of Gravity Device with Subject in Supine Standing (upper) and Supine Sitting Position(lower).

ments of vertical (anterior-posterior) center of gravity in the supine standing position unreliable. In this study, therefore, the center of gravity above the platform is reported only for the supine sitting position. During the center of gravity measuring sequence the computer program advances through the sequence of eight positions shown in Figure 13 sampling the load cells in each position when a

Figure 13. Sequence of Center of Gravity Device Position

keyboard key is depressed. Upon completing the series, the computer displays the results and compares the calculated weight with the value of the scale weight previously entered. If a significant difference in the two weights exists, the computer rejects the center of gravity data and displays a request to repeat the measurement.

During the center of gravity measuring process, the supine

standing height and sitting height are measured while the subject is lying on the platform. The plexiglass device shown in Figure 14 is aligned with the measuring tape attached to the C.G. platform and

Figure 14. Plexiglass Device for Measuring Supine Stature and Sitting Height Aligned with Tape on C.G. Platform

placed against the top of the subject's head. The tape reading at the intersection with the plexiglass head plate is typed into the computer. These supine measures are used to describe the center of gravity results as a percent of standing and sitting height. The seated center of gravity distance above the platform (anterior/posterior) is also presented as a percent of buttock-knee length.

A foot rest extension shown in Figure 15 is removable and is used in taking center of gravity measurements on large subjects. By shifting the center of gravity further toward the end with two load cells (i.e., toward the wheels) and away from the single load cell end, this device allows heavier subjects to be measured and facilitates tilting of the platform. Before beginning a center of

Figure 15. Center of Gravity Foot Rest Extension

gravity measurement sequence the computer requires an input as to whether this extension is being used. In this way the distance of the center of gravity from the foot reference plane can always be calculated.

3. Instrument Calibration

The transducing cells on the center of gravity devices were calibrated before field measuring began and periodically checked when the equipment was returned to HSRI. The other measuring devices including the anthropometers, sliding calipers, and girth devices were calibrated each day or each time the computer was turned on. Length was calibrated by sequencing through a number of predetermined positions along the scale of each device. At each distance the potentiometer voltage was sensed when the device button was depressed. For the calipers, five points were taken and a least squares linear regression fitted to the data. For the anthropometers and girth devices, two linear regressions were used. One, for computing distances less than 25 centimeters, was fitted to six points at 5, 10,

15, 20, 25 and 35 centimeters. The other, for distances greater than 25 centimeters, was fitted to six points at 20, 35, 50, 65, 80 and 90 centimeters. The regression coefficients were stored and used for converting A/D values to measurement distances during the measurement process.

Pressure transducers were calibrated by using a dial pressure gauge and child size blood pressure bag as illustrated in Figure 16. The surface of the bag was placed evenly over the transducer and the bag inflated. Pressure was then exerted on the bag with the fingers or palm of the hand until the dial read the desired pressure. The

Figure 16. Pressure Transducer Calibration Procedure Using Dial Pressure Gauge and Child Size Blood Pressure Bag.

inflation of the bag was maintained so that only the air pressure transmitted through the bag wall pressed against the transducer. Three pressures at 50, 30 and 0 mm Hg were used for calibration and a linear regression fitted to the data.

While the computer program automatically sequences through the calibration of all the instruments when the data acquisition program

is begun, it is possible to recalibrate any instrument at any time during the measurement process. This was useful if an instrument's calibration was suspected or if any instrument was replaced due to a device failure.

4. Data Acquisition Program

a. General Description. The process of collecting anthropometric and demographic data is controlled by a fairly sophisticated program called the Michigan Anthropometric Processor or MAP. This program contains routines for calibrating equipment, sensing which measuring device is being used, editing and storing data on magnetic tape, sequencing through the measurements and demographic questions, and informing the anthropometrist when a measurement value seems inappropriate in relation to the subject's age, weight or stature. In addition, the program provides several options to the investigator such as skipping forward or back to a particular measurement, redoing a measurement at the end of the sequence, listing all data for review, overriding the use of an automated device in case of a device failure, and deleting a subject or selected measurements at the end of a measurement sequence. The program also selects on a rotating basis the particular measurement set (shape, linkage, or head, face and hands) to be taken on each subject, thereby eliminating any measurer bias and insuring an equal number of subjects at each location for each data set.

b. Demographic Information. The program automatically assigns a number to each subject based on the data tape number and the number of subjects already on the tape. For example, the eleventh subject on data tape 130 would be assigned subject number 130011. For each new subject the program initially requires the measurer to input the approximate age and height. The remainder of the demographic data was usually typed into the computer upon completion of the measuring process, although the option is also provided for doing this before measuring. The date and location are input only once each time the computer is started up since these will remain the

same for all subjects measured at that time. Upon input of the subject's birthdate, the computer calculates the precise age of the subject and compares this with the approximate age previously input, thereby insuring that an accurate measure of age is obtained. Where feasible, and in order to minimize errors in the demographic data, information is typed in using words, and numerical codes are assigned by the program. For example, sex is entered as "Male" or "Female" and assigned codes 1 and 2 respectively. For each subject measured, a number corresponding to the person taking the measurement is also typed in.

Upon completion of the interview routine, the computer program asks for any comments about the subject which may be useful in editing the data (e.g., very large for age) or indicate a factor (e.g., serious illness) which could affect the child's physical size. In addition to writing this message, the comments were coded in a six digit number in which two adjacent numbers comprise one comment code (e.g., 050300 indicates a heavy, tall subject). It was thus possible to code three different comments on a subject which could be referred to during data editing.

c. Measurement Information. With regard to the process of obtaining measurement data itself, there are several ways in which a measurement may be taken. For a few measurements such as weight, bitracion breadth, and finger diameters, the measurement is read manually (i.e., visually) and typed into the computer. For all other measurements, the measurement distance is retrieved electronically, and is activated on the particular device in use by depressing a button on the measurement device.

For most of these automated measurements, the electrical signal is read at the time the button is depressed. For some measurements, however, where soft tissue is a major factor (e.g., shoulder breadth), the measurement signal is recorded at a specified value of pressure as measured by the pressure transducer in the moving plexi-glass blade of the calipers or anthropometer. In taking these soft

tissue measurements, the computer assumes that zero pressure is applied at the time the device button is depressed and uses the slope of this regression line to determine the applied pressure during a measurement "squeeze". By this procedure, variations in the pressure due to transducer offset shifts are eliminated. For each measurement "squeeze" on soft tissue, 20 lengths at 20 pressures are recorded from 0 to 1 PSI. Only the distances at .1 PSI (light contact) are reported in this study.

While for most measurements the electrical signal into an A/D channel is converted to a measurement distance using calibration regression coefficients determined for each instrument at the beginning of a measuring session, in many cases some further computations are necessary. For example, for certain measures such as thumb crotch-middle finger length or thumb-middle finger grip length, the distance across the anthropometer housing or the width of the instrument blades comprise part of the measurement distance. These fixed distances must be added to the distance between inside surfaces of the blades as calculated from the electrical readout.

For another group of measurements which are referred to in this study as "tare" measurements, the distance of interest is not that between blades, but rather the distance between the sliding blade and the extension end of the anthropometer. An example of such a measurement is stature, where the outside edge of the moving plexiglass blade is placed in contact with the top of the subject's head while the extension end of the anthropometer is on the standing surface. Since the computer receives an electrical signal proportional to the distance between the paddle blades, a calculation must be made to determine the distance from the bottom of the moving blade to the floor. Thus, the length of the instrumented portion of the anthropometer, the thickness of the moving paddle blade, and the length and number of any extensions must be known and added to the anthropometer. All of these distances are standardized and can therefore be fixed in the computer program. To determine the number of extensions used in a particular "tare" measurement, the computer pro-

gram relies on the approximate subject height, which is typed in when a new subject is begun, and the high correlation between stature (which is the first "tare" measure taken) and the other "tare" measurements.

As each measurement is taken, it is checked against a table of measurement minimum and maximum values based on the age of the subject. If the measurement is not within the range of the table, the measurer is notified on the display screen with a special message. The measurer then has the option of accepting or retaking the measurement. Also, after any measurement is taken, the measurer has the option of retaking it, retaking a previous measurement, or deleting all measurements and starting the measurement sequence again. Upon completing the measurement set, the measurer may list all the measurements and delete or repeat any measurement that is in error.

As with sampling of the center of gravity transducing cells, the actual signal used for measurement computations is an average of several A/D readings taken in a short time interval (approximately 16 samples in 1 msec). This is done to average out high frequency noise imposed on the signals by the computer or other external electrical devices. The result is a measurement device repeatability far more accurate than measurer repeatability.

5. Other Measuring Equipment

In addition to the automated devices described above, several other measuring tools were used in taking these anthropometric data. Thumb and finger diameter measurements were taken using the holes in a drafting template, while hand clearance measurements were taken using a set of hinged plexi-glass boards containing various-sized holes as illustrated in Figure 17. In all these devices the hole dimensions were coded and the code typed into the computer at the time of measuring. Since the hole size in a drafting template is not exactly the dimension written on the template by the manufacturer

Figure 17. Drafting Template and Hinged Plexi-glass Boards for Measuring Finger Diameters and Hand Clearance.

(i.e., the hole allows for pencil thickness), these holes were individually measured in order to construct the conversion table.

The grip bar attached to the pivoting extension rod shown in Figure 18 was used for taking functional grip reach measurements. This device not only helped the measurer to align (square) the position of the arm relative to the horizontal or vertical, but simplified the measuring of vertical arm reach on tall subjects. Instead of measuring to the top of the grip bar, the anthropometrist measures to the bottom of the extension rod and the computer program adds the fixed distance from the bottom of the rod to the top of the grip bar.

Other equipment which facilitated the measuring process considerably are the specially constructed portable table and adjustable foot rest platform shown in Figure 19. These devices allowed the measurers to orient the subject in any position and at various levels

Figure 18. Grip Bar and Pivoting Extension Rod Used for Functional Reach Measurements.

Figure 19. Portable Measuring Table (left) and Adjustable Foot Rest (right) Used for Orienting Subjects in Desired Positions.

from the floor for greatest ease and accuracy in taking any measurement.

Two complete sets of all equipment were assembled, including a standard spreading caliper for measuring bitracion breadth, and

carried along with the automated instruments in suitcases with specially designed foam inserts for instrument protection. In addition, a third suitcase containing an extra set of automated devices was carried between the two teams and used as backup in case of an instrument failure.

All equipment, including computers, table, anthropometers, center of gravity devices, display screens, infant and standard scales and related devices was transported to measurement locations by two Dodge Maxi-Vans. The interior of the vans were modified for securing all equipment in a safe and stable manner and specially designed light weight ramps were utilized for moving the computers in and out of the vans as illustrated in Figure 20.

Figure 20. Computer Being Unloaded From Dodge Maxi-Van Using Specially Designed Light Weight Ramps.

6. Standard Measuring

For the case where an automated device became non-functional and a back-up device was not immediately available, the

computer program allowed for overriding the automated data storage and for accepting data typed in via the keyboard. In these cases the measurers could continue to use the modified instrument or could switch to a standard anthropometric device. In either case, however, the measurement was read visually off the scale. This particular situation happened only infrequently and was used only as a temporary procedure to prevent the teams from falling behind in their measuring schedule.

In other cases, due to the construction or size of a particular facility, it was not possible to use the computer system at all. In general, these conditions were avoided in the public schools, but this was not always possible, especially during the summer when a good deal of measuring took place in camps. In these instances, measurements were taken with standard anthropometric instruments equipped appropriately with paddle and pointed blades, and measurements were recorded on prepared forms.

7. Data Handling, Editing, and Analysis Procedures

Measurement and demographic data obtained in the field were recorded either on Linc magnetic tape by the computer system or on measurement forms by hand if the computer could not be used. The former technique was used in most locations and thus digital tapes constitute most of the data. At the completion of each geographic location the data were returned to HSRI for transfer to a common file on the Michigan Terminal Computer System (MTS). Tape data were first copied to a DEC tape which could be read by the HSRI PDP 11/45 computer system and transferred to 9-track magnetic tape. These tapes could then be read directly by MTS. Hand-recorded data was keypunched onto IBM cards at HSRI and read into MTS directly. Prior to keypunching these data, the demographic information was hand coded in the right hand column of the questionnaire (see Figure 5). A subject number was assigned at this time beginning with 300001 for 2 through 18 year olds and 450001 for infants. Code numbers denoting the measurement

set and measurer were also included.

While much editing of the data took place continuously as data were collected by the MAP program or immediately after transfer to MTS, final editing could not be accomplished until all measuring was completed and all data were in common file. At this time the data were brought back to the HSRI PDP 11/45 system for editing by two procedures.

A program called X-VAL, obtained from anthropologists at Wright-Patterson AFB, was used to search for extreme measurement values in designated age groups. Subjects were grouped by data set, sex, and age intervals of one year each, and the program listed the ten smallest and ten largest values for each measurement along with statistics of the distribution (e.g., mean, standard deviation, skewness). Visual inspection of the data was then used to search for subject numbers with unreasonable measurement values and a complete listing of the data on these subjects, including the comments and comment code, was produced. From this listing a decision could be made as to whether to delete or leave the value in question. Substitutions in the data were made only in instances in which the error was obviously a transposition of digits.

A second procedure used to edit the data was multiple regression analysis. This involved establishing a linear relationship between one measurement variable and several other measurement variables. For example, one might attempt to establish a linear relationship of weight with stature, chest circumference, and waist circumference [weight = f (stature, chest circ., waist circ.)]. Once a relationship was established, measurement values which fell outside the predicted value, plus or minus specified error tolerances, were edited appropriately. This procedure allowed for editing points which were incorrect but which still fell within two standard deviations of the mean measurement value for a given age range (i.e., they are not extreme values). Because of the small effect of such points on the statistics of a particular age group and the time required to

do this editing, this procedure was only used for those measurements included in the bivariate analysis results in Section D of Chapter III. The program used to complete this task was also implemented on the HSRI PDP 11/45 computer system.

CHAPTER III

RESULTS

In this Chapter the results are presented in five major sections. In Section A, a breakdown of the sample by demographic information is presented along with results from statistical comparisons of selected core measurements taken in the three measurement set samples. Sections B through D present the results for measurements taken on 2-18 year olds in three ways that will be useful to product designers and other users of these data. Section E contains the results for infants (0-24 months) and Section F is a glossary of anatomical and anthropometric terms used in the measurement descriptions.

A. Description of Sample and Comparison of Measurement Sets.

1. Description of Sample

Table 1 shows a breakdown of the sample by sex and race. This consists of a total of 4127 subjects of which 2092 (50.7%) are male and 2035 (49.3%) are female. Of this 4127, 3570, or 86.5 percent are white; 452, or 11.0 percent, are black; 37, or .9 percent, are oriental; and 6, or .1 percent, are American Indian. Sixty two, or 1.5 percent, were classified as "other" indicating either bi-racial or unknown race. These percentages are nearly identical for males and females with the exception of American Indians where only one out of six was female. Table 2 shows this racial breakdown by age intervals and demonstrates that these percentages are consistent across the age range of the study.

Concerning geographic location, Appendix A is a list of those schools, camps, nurseries, clinics, and other locations at which measuring took place arranged by eight geographic regions. A total of 104 measurement sites were used in this study, although some have been consolidated into a single name in this listing. Table 3

shows the distribution of the sample by geographic region and sex. Approximately equal numbers of males and females were measured in each region. The largest number of subjects were measured in the midwest primarily due to the fact that most infants and a large percentage of preschoolers were measured in the Ann Arbor-Detroit area. Figure 21 shows an outline of the United states and indicates this geographic distribution of measurement sites more graphically.

2. Comparison of Measurements Between Measurement Set Populations.

As mentioned in Chapter II, the measurement strategy produced three different sets of subjects. In order to compare the three separate measurement set samples, an analysis of variance test was used on the mean values of several of the core variables measured on every subject. Tests were run for seven age intervals (2-4, 4-5, 6-9, 9-11, 11-13, 13-15 and 15-19) for weight, stature, head circumference, waist circumference, shoulder breadth, maximum hip breadth, and erect sitting height. For every test but one (weight for 2-4 years) there was no significant difference between mean values of the measurement distributions for the three data sets at the .05 level of significance. From these results it can be concluded that measurements from the three sets were from similar populations and can be combined for purposes of data presentation.

B. Measurement Results Versus Age for Subjects 2-18 Years.

In this section the measurement results versus subject age are presented for the 87 measurements taken on 2 through 18 year olds.¹ The results for each measurement are presented in a 4-page format. On the first page the measurement name and description are given along with a photograph of the measurement and illustration. On the second page, a table of summary statistical results for 16 age

¹ All results in this report are given in metric units (i.e., cm., mm., kg). To convert length in centimeters to inches divide by 2.54. To convert kilograms (kg) to pounds (lbs) multiply by 2.2.

Figure 21. Map of United States Showing Measurement Location Sites.

groups and a scatter plot¹ of the measurement values versus subject age for males and females combined are given. The third page contains the tables of summary statistics for males and females separately while the fourth page contains the scatter plots for males and females separately.

In the measurement descriptions, anatomical and anthropometric terms have been used where necessary. Where a brief definition of these terms is possible, this has been placed in parentheses next to the technical term. More complete definitions of all these terms can be found in the glossary in Section F of this chapter.

For the tabular results, subjects have been divided into one year age groups centered about integer years (e.g., $3\frac{1}{2}$ - $4\frac{1}{2}$, $4\frac{1}{2}$ - $5\frac{1}{2}$) except for the first and last groups which are for $1\frac{1}{2}$ years each (i.e., $2-3\frac{1}{2}$, $17\frac{1}{2}-19$). For each age group the sample size (N), mean, standard deviation, 5th, 50th, and 95th percentiles, and minimum and maximum values are given. Percentiles are calculated by interpolating between values of the measurement which lie on either side of the percentile of interest. For example, if the measurement values up to 6.5 include 4.8 percent of the sample and the next higher value of 10.5 includes 5.3 percent of the sample, then the 5th percentile is computed as $6.5 + (10.5 - 6.5) \left(\frac{5.0 - 4.8}{5.3 - 4.8} \right) = 6.5 + 4 \left(\frac{.2}{.5} \right) = 8.1$. If there are less than 20 values in the sample, the 5th and 95th percentiles are not calculated and asterisks are substituted in these columns.

In scatter plots, each data point is plotted using the symbol x for females and + for males. The measurements are presented in the order illustrated in Figure 22 and divided into four groups according to measurement type and body region. Group A consists of weight, stature and standing and sitting measurements; Group B is measurements of the head, face, and neck; Group C consists of

¹ An error in labeling the ordinate axes of these plots has been made in that accuracy to two decimal places is indicated. In fact, all measurement values have been rounded off to the nearest single decimal place.

Group A. Weight, Stature, Standing
and Sitting Measurements

1. Weight
2. Stature
3. Vertical Grip Reach
4. Frontal Grip Reach
5. Lateral Grip Reach
6. Step Height
7. Supine Stature
8. Standing Center of Gravity
9. Erect Sitting Height
10. Eye Height (Seated)
11. Maximum Hip Breadth (Seated)
12. Maximum Thigh Breadth (Seated)
13. Thigh Clearance
14. Buttock-Knee Length
15. Knee Height
16. Supine Sitting Height
17. Seated Center of Gravity

Group B. Head, Face and Neck Measurements

18. Head Circumference
19. Head Breadth
20. Head Length
21. Bizygomatic Breadth
22. Frontal Breadth
23. Lower Face Height
24. Face Height
25. Head Height
26. Trasion to Back of Head
27. Trasion to Top of Head
28. Ear-Sellion Depth
29. Bitrasion Breadth
30. Mouth Breadth
31. Nose Length
32. Neck Circumference
33. Lateral Neck Breadth

54. Index Finger Diameter	81. Calf Circumference
55. Middle Finger Length	82. Calf Depth
56. Middle Finger Diameter	83. Ankle Circumference
57. Middle Finger-Thumb Grip Length	84. Ankle Breadth
58. Maximum Fist Circumference	85. Sphyrion Height
59. Maximum Fist Breadth	86. Foot Length
60. Maximum Fist Depth	87. Foot Breadth

Figure 22. (continued)

measurements of the shoulders, arm, and hands; and Group D contains measurements of the chest, torso, pelvis, legs and feet. For purposes of simplifying the procedure of searching for a measurement or measurements on a particular body region, the results for measurements in these four groups are presented on different colored pages as listed below.

- A. Weight, stature, standing and sitting measurements - blue
- B. Head, face, and neck measurements - yellow
- C. Shoulder, arm, and hand measurements - green
- D. Torso, pelvis, legs, and foot measurements - gold

Corresponding colors are used on the index pages preceding these results (Figures 23-27) which illustrate the measurements along with the measurement numbers. These numbers are also displayed in parentheses in the upper left or right hand corner of the pages of results in this section.

VERTICAL GRIP REACH

Subject stands erect with feet together, right side against wall, grasping the handle of the grip device in right hand, extending right arm to maximum vertical reach. With the pointed blade of an automated anthropometer, measure the vertical distance from the floor to the most distal point on the handle of the grip device.

STEP HEIGHT

Subject stands erect facing wall with palms of hands resting lightly against wall at shoulder level for balance. Subject raises right foot to maximum height from floor. With the paddle blade of an automated anthropometer, measure the vertical distance from the floor to the ball of the foot.

(7)

SUPINE STATURE

Subject lies on back on the CG device with feet firmly against the foot reference plane. The arms are placed at the sides with the legs straight. Using the block and tape on the CG device, measure the location of the top of the head. The measurement is typed into the computer and the distance from the foot reference plane to the top of the head is computed.

STANDING CENTER OF GRAVITY

Subject lies on back on the CG device with the feet placed firmly against the foot reference plane. The arms are placed at the sides with the legs straight. The horizontal distance of the center of gravity from the reference plane (D_1) is computed. The distance is reported as measured and as a percent of supine stature. $[(D_1/\text{supine stature}) \times 100]$.

ERECT SITTING HEIGHT

Subject sits erect with head oriented in the Frankfort Plane, arms hanging at sides. With the paddle blade of an automated anthropometer, measure the vertical distance from the sitting surface to vertex (top of the head).

MAXIMUM THIGH BREADTH, SITTING

Subject sits erect with knees together, feet resting on a platform adjusted for 90° flexion. With the paddle blades of an automated anthropometer, measure the maximum breadth across the thighs at a fixed pressure value.

(15)

KNEE HEIGHT

Subject sits erect, feet resting on a platform adjusted for 90° knee flexion. With the paddle blade of an automated anthropometer, measure the vertical distance from the foot-resting surface to the top of the right knee, just in back and above the patella (knee cap).

SUPINE SITTING HEIGHT

Subject lies on back on the CG device with legs placed over the adjustable support so that the knees form a 90 degree angle, the buttocks are firmly against the reference plane, and the upper legs are approximately 90 degrees to the torso. The arms are placed at the sides. Using the block and tape on the CG device, measure the location of the top of the head. The measurement is typed into the computer and the distance from the buttocks reference plane to the top of the head is computed.

SEATED CENTER OF GRAVITY

Subject lies on back on the CG device with legs placed over the adjustable support so that the knees form a 90° angle, the buttocks are firmly against the reference plane, and the upper legs are approximately 90° to the torso. The arms are placed at the sides. The horizontal distance of the center of gravity from the buttocks reference plane (D_2) and vertical distance of the center of gravity from the CG platform (D_3) are computed. The horizontal distance is reported as measured and as a percent of supine sitting height $[(D_2/\text{supine sitting ht}) \times 100]$. The vertical distance is also reported as measured and as a percent of buttock-knee length $[(D_3/\text{buttock-knee L}) \times 100]$.

HEAD, FACE, AND NECK MEASUREMENTS

HEAD CIRCUMFERENCE

Subject stands erect, arms hanging at sides. With an automated tape device, measure the circumference of the head at the level of the plane passing above glabella (most anterior protrusion of forehead) and through opisthocranium (most posterior protrusion from glabella on the back of the head), perpendicular to the mid-sagittal plane.

HEAD CIRCUMFERENCE (cm)
(Males and Females)

HEAD BREADTH

Subject sits erect with head oriented in the Frankfort Plane, arms hanging at sides. With the paddle blades of an automated sliding caliper, measure the maximum breadth of the head above and behind the ears.

HEAD LENGTH

Subject stands erect with head oriented in the Frankfort Plane. With the paddle blades of an automated anthropometer or sliding caliper, measure the distance from the glabella (most anterior protrusion of the forehead) to opisthocranium (most posterior point from glabella on the back of the head).

HEAD HEIGHT

Subject sits erect with head oriented in the Frankfort Plane with jaws closed. With the pointed blades of an automated anthropometer, measure the height of the head perpendicular to the Frankfort Plane from menton to vertex.

BITRAGION BREADTH

Subject sits erect with head oriented in the Frankfort Plane. With spreading calipers, measure the distance from right to left tragon. The measurement is typed into the computer.

NECK CIRCUMFERENCE

Subject stands erect with head oriented in the Frankfort Plane. With an automated tape device, measure the circumference of the neck perpendicular to the long axis of the neck at the mid-point.

SHOULDER, ARM, AND HAND MEASUREMENTS

(34)

CLAVICALE-ACROMION LENGTH

Subject stands erect, arms hanging at sides. With the pointed blades of an automated anthropometer, measure the distance between right clavicle and right acromion.

SHOULDER BREADTH

Subject stands erect, upper arms at sides, and elbows flexed 90°. With the paddle blades of an automated anthropometer, measure the horizontal breadth across the shoulders at a fixed pressure value.

(41)

ELBOW-HAND LENGTH (LOWER ARM LENGTH)

Subject stands erect, upper arms hanging at sides and elbows flexed 90° with hands and fingers extended. With the paddle blades of an automated anthropometer, measure the distance from the posterior surface of the right upper arm just above the elbow to the tip of the middle finger parallel to the long axis of the forearm.

WRIST CIRCUMFERENCE

Subject stands erect, arms hanging at sides. With an automated tape device, measure the minimum circumference of the right wrist above the distal (ulna) styloid process.

MINIMUM HAND CLEARANCE

Subject extends right hand reduced to its narrowest configuration. With a hand measurement board, record the smallest diameter through which the hand can pass without forcing it. The measurement is typed into the computer.

THUMB CROTCH-MIDDLE FINGER LENGTH

Subject extends right hand and fingers with palm up, thumb away (abducted) from hand. With an automated sliding caliper, measure the distance from the crotch of the thumb to the tip of middle finger parallel to the fingers. A constant correction factor for the caliper blade offset is added to the measurement.

(56)

MIDDLE FINGER DIAMETER

Subject extends middle finger of right hand. With a finger measurement board, record the greatest diameter through which the first joint of the middle finger cannot pass. The measurement is typed into the computer.

CHEST HEIGHT AT AXILLA

Subject stands erect, with feet together, weight evenly distributed, arms initially raised then lowered when instrument is in place. With the pointed blade of an automated anthropometer, measure the vertical distance from the standing surface to the right axilla (armpit).

(65)

WAIST HEIGHT

Subject stands erect with feet together and weight evenly distributed. With the pointed blade of an automated anthropometer, measure the vertical distance from the standing surface to the umbilicus (navel).

ILIOCRISTALE (PELVIS) HEIGHT

Subject stands erect with feet together, weight evenly distributed. With the pointed blade of an automated anthropometer, measure the vertical distance from the standing surface to the highest point on the right iliac crest of the pelvis.

HIP BREADTH AT TROCHANTER

Subject stands erect with feet together, weight evenly distributed. With the paddle blades of an automated anthropometer, measure the horizontal distance between the right and left greater trochanter landmarks.

GLUTEAL FURROW HEIGHT

Subject stands erect with feet together, weight evenly distributed. With the pointed blade of an automated anthropometer, measure the vertical distance from the standing surface to the lowest point where the buttock curve and the back of the right thigh join.

(78)

UPPER THIGH DEPTH

Subject stands erect with feet together and weight evenly distributed. With the paddle blades of an automated anthropometer or sliding caliper, measure the horizontal depth (anterior-posterior) of the right thigh at the level of the gluteal furrow at a fixed pressure value.

SPHYRION HEIGHT

Subject stands erect with feet apart, weight evenly distributed. With the pointed blade of an automated anthropometer, measure the vertical distance from the floor to right sphyrion. The constant height from the floor to the standing surface is subtracted to give the height from the standing surface to sphyrion.

C. Measurement Statistics by Body Region and Age Group for Subjects 2-18 Years.

This section is included to facilitate data retrieval for users who need information on several measurements of a similar type (e.g., hand measurements) and for a particular age group. Each table contains all the measurements in one of the four measurement groups (see Figure 22) for one of the sixteen age intervals. Tables for combined sexes, and males and females are given separately for a total of 192 tables in all. In order to facilitate the use of this section, tables for each of the four measurement groups are printed on colored paper corresponding to the colors used in Section B. All measurements are given in metric units. Weight is in kilograms, finger and thumb diameter and hand clearance are in millimeters, and all other dimensions are in centimeters (see page 43 for conversion to inches and pounds).

WEIGHT, STATURE, STANDING AND SITTING MEASUREMENTS

WEIGHT, STATURE, STANDING, AND SITTING MEASUREMENTS
(Males and Females - Ages 2.0 to 3.5 Years)

D. Bivariate Relationships of Selected Measurements with Stature and Weight.

It is often the case that an investigator or designer knows the height and weight and possibly a few other basic measurements on a specific population of individuals with which he is concerned and would like to know something about other measurements, perhaps of a more functional nature. For example, one might know the average or mean weight and age of a group of individuals and would like to know what the seated hip breadth (e.g., for seat design) for this population would be.

In this section, the regression and correlation coefficients which describe the relationships between selected functional measurements taken in this study and stature or weight are given. These coefficients are tabulated by males and females separately and for seven age groups over the range 2-19 years. Along with these tables a scatter plot showing visually the relationship between the two measurement variables is also given for males and females combined.

The linear regression equation provides a quick way of approximating one measurement given another, plus or minus some expected error given by the standard error of the regression. The correlation value in the table assigns the degree of linear relationship between the two measurements. Correlation values range from -1 to $+1$, where values greater than zero indicate that small values of one measurement are, in general, associated with small values of the other, and large values of one measurement are associated with large values of the other. If the correlation is negative, the inverse relationship holds. A value close to ± 1 indicates an almost perfect linear relationship.

Thus, given the linear regression coefficient, regression constant, and regression standard error which describes the relationship of one dependent measurement variable (V_1) with respect to a second independent variable (V_2), one can then estimate V_1 given V_2 on any individual or for any population which meet the age and sex criteria

of the sample population from which the coefficients were derived.
That is:

$$V1 = \text{regression coeff.} \times V2 + \text{regression constant} \pm \text{standard error.}$$

The following measurements have been selected for regression analysis with stature or weight and are presented in the order given in this section.

<u>With Stature</u>	<u>Page Number</u>

E. Infant Measurement Results

This section contains the statistical results for the 34 measurements taken on infants less than 24 months old. The presentation of these data is divided into three parts. In the first part the measurement descriptions along with photograph and illustration are given along with the scatter plot of measurement values versus age and summary statistics for males and females combined for seven age intervals. These results are presented on one page for each measurement and in the order shown in Figure 28. The numbers on the index pages preceding these results (Figure 29) correspond to the measurement numbers in this list and also appear in parentheses in the upper left or right hand corner of the data pages. In the second part of this section the infant statistical results are presented in tables by age group and in the third part (Figure 30) a weight versus stature scatter plot for infants is shown.

(1)

WEIGHT

The diapered infant is placed on a clinical scale and weighed to the nearest tenth of a kilogram. The measurement is typed into the computer.

WEIGHT (kg)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	30	5.1	1.1	3.1	3.2	4.7	6.9	8.0
3-5	29	6.9	1.0	4.7	4.9	6.7	8.2	9.2
6-8	28	8.1	0.9	6.4	6.4	8.0	9.4	10.0
9-11	22	9.2	1.1	6.9	7.0	9.1	10.9	11.1
12-15	28	10.1	1.2	8.3	8.4	10.0	12.6	13.0
16-19	19	10.6	1.2	8.3	**	10.6	**	13.5
20-23	24	11.5	1.5	7.5	7.8	11.6	13.2	15.3

CROWN-SOLE LENGTH

Infant lies on back with legs extended; the head is aligned in the Frankfort Plane relative to the extended torso (the head faces forward). With the paddle blades of an automated anthropometer, measure the distance from vertex (top of head) to the heel of the right foot. An assistant is required to assure that the infant is in the correct position.

CROWN-SOLE LENGTH (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	31	56.3	3.9	50.5	50.7	55.5	63.3	64.1
3-5	45	63.1	3.6	54.1	56.2	63.3	68.2	69.1
6-8	31	68.5	2.6	63.4	64.2	68.7	72.2	72.8
9-11	26	73.0	3.3	65.9	66.2	73.0	77.4	79.1
12-15	32	76.5	3.2	69.4	69.8	76.7	80.7	84.8
16-19	27	79.2	3.4	72.3	72.6	79.0	84.6	85.9
20-23	31	82.6	4.0	73.6	74.4	82.5	88.3	89.8

(3)

CROWN-RUMP LENGTH

The infant lies on back with right leg flexed 90° to torso so that rotation of the pelvis is minimal; the head is aligned in the Frankfort Plane relative to the torso (the head faces forward). With the paddle blades of an automated anthropometer, measure the distance from vertex to the surface of the right buttock. An assistant is required to assure that the infant is in the correct position.

CROWN-RUMP LENGTH (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	31	39.1	2.8	34.5	34.7	38.4	43.0	44.3
3-5	45	42.3	2.4	36.4	37.5	42.2	45.8	48.0
6-8	31	45.7	2.3	42.2	42.3	45.3	50.0	51.5
9-11	26	47.6	2.2	42.8	43.3	48.0	50.7	53.0
12-15	32	49.0	2.1	44.2	44.6	48.9	51.8	52.2
16-19	29	49.8	2.0	45.8	46.6	49.1	53.5	55.1
20-23	31	51.5	2.4	46.0	46.9	51.5	54.9	55.2

HEAD CIRCUMFERENCE

The infant's head is supported away from table surface. With an automated tape device, measure the circumference of the head at the level of the plane passing above the glabella (the most anterior protrusion of the forehead) and over the opisthocranium (the most posterior protrusion from glabella on the back of the head), perpendicular to the mid-sagittal plane. An assistant is required to assure that the infant is in the correct position.

HEAD CIRCUMFERENCE (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	30	38.5	1.9	35.3	35.4	38.8	41.2	42.2
3-5	44	41.7	1.4	38.9	39.6	41.8	44.0	44.7
6-8	28	43.9	1.3	42.1	42.1	43.7	45.8	46.8
9-11	27	45.5	1.4	43.1	43.1	45.5	47.5	48.4
12-15	29	46.6	1.4	43.8	44.1	46.6	48.5	50.0
16-19	27	46.8	1.8	43.1	43.4	46.1	49.8	50.0
20-23	31	47.8	1.9	44.6	44.6	47.7	50.8	51.2

(5)

HEAD BREADTH

The infant is placed in a sitting position. With the paddle blades of an automated sliding caliper, measure the maximum breadth of the head above and behind the ears. An assistant is required to assure that the infant is in the correct position.

HEAD BREADTH (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	31	10.4	0.5	9.5	9.5	10.3	11.2	11.3
3-5	44	11.4	0.5	10.4	10.5	11.3	12.2	12.3
6-8	30	11.8	0.4	11.1	11.1	11.8	12.4	12.6
9-11	27	12.2	0.5	11.3	11.4	12.1	12.9	13.6
12-15	31	12.7	0.4	12.0	12.0	12.7	13.5	13.6
16-19	29	12.7	0.4	11.8	11.9	12.6	13.2	13.3
20-23	31	12.9	0.5	12.1	12.1	12.9	13.6	13.7

HEAD LENGTH

The infant's head is supported free from table surface. With an automated sliding caliper, measure the distance from glabella (most anterior protrusion of the forehead) to opisthocranium (the most posterior point from glabella or the back of the head). An assistant is required to assure that the infant is in the correct position.

HEAD LENGTH (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	31	13.4	0.8	12.2	12.3	13.4	14.7	15.1

9-11	27	16.0	0.7	14.5	14.7	16.1	16.8	17.9
12-15	31	16.7	0.7	15.5	15.6	16.5	17.6	18.8
16-19	29	16.7	0.7	15.3	15.5	16.5	17.8	18.0
20-23	31	17.1	0.8	15.7	15.7	17.2	18.4	18.6

(7)

SHOULDER BREADTH

The infant lies on back with upper arms resting against body. With the paddle blades of an automated anthropometer or sliding caliper, measure the breadth across the shoulders at a fixed pressure value. An assistant is required to assure that the infant is in the correct position.

**SHOULDER BREADTH (cm)
(Males and Females)**

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max

20-23	31	22.4	1.3	20.1	20.3	22.1	23.9	25.5

SHOULDER-ELBOW LENGTH

The infant lies on back with right upper arm resting against body and right elbow flexed 90°. With the paddle blades of an automated sliding caliper, measure the distance from the superior surface of the right shoulder to the inferior surface of the right elbow parallel to the long axis of the upperarm. An assistant is required to assure that the infant is in the correct position.

SHOULDER-ELBOW LENGTH (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	31	10.9	0.9	9.3	9.3	10.9	12.4	12.7

20-23	31	15.0	1.0	12.2	12.9	15.0	16.3	16.8

ELBOW-HAND LENGTH

The infant lies on back with right elbow flexed 90° and right hand and fingers extended. With the paddle blades of an automated anthropometer or sliding caliper, measure the distance from the posterior surface of the right upper arm, just above the elbow, to the tip of the middle finger of the right hand parallel to the long axis of the forearm. An assistant is required to assure that the infant is in the correct position.

ELBOW-HAND LENGTH (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max

20-23	31	4.7	0.3	4.1	4.2	4.6	5.2	5.6

MINIMUM HAND CLEARANCE

The fingers of the right hand are extended and placed together so as to form the narrowest configuration. With a hand measurement board, record the smallest diameter through which the measurer can pull the infant's right hand. The measurement is typed into the computer. An assistant is required to assure that the infant is in the correct position.

MINIMUM HAND CLEARANCE (mm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max

MID-THIGH CIRCUMFERENCE

The infant lies on back with right leg extended. With an automated tape device, measure the circumference of the right leg midway between the abdomen-thigh flexure crease and the knee. An assistant is required to assure that the infant is in the correct position.

MID THIGH CIRCUMFERENCE (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max

20-23	31	24.7	2.5	18.1	19.0	24.6	27.6	29.9

MID-THIGH DEPTH

The infant lies on back with right leg supported free of table surface. With the paddle blades of an automated sliding caliper, measure the depth midway between the abdomen-thigh flexure crease and the knee at a fixed pressure value. An assistant is required to assure that the infant is in the correct position.

MID THIGH DEPTH (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max

20-23	30	7.2	1.0	4.9	4.9	7.1	8.6	8.8

KNEE-SOLE LENGTH

Infant lies on back with the right knee flexed 90°. With the paddle blades of an automated anthropometer, measure the distance from the superior surface of the right knee to the heel of the right foot. An assistant is required to assure that the infant is in the correct position.

KNEE-SOLE LENGTH (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	30	14.9	1.1	12.8	13.0	14.7	16.5	17.4

20-23	31	23.0	1.6	18.8	19.8	22.9	25.3	26.4

CALF CIRCUMFERENCE

The infant lies on back with right leg extended. With an automated tape device, measure the maximum circumference at the level of the greatest posterior protrusion of the calf. An assistant is required to assure that the infant is in the correct position.

CALF CIRCUMFERENCE (cm)
(Males and Females)

Age (mos)	N	Mean	s.d.	Min	5th	50th	95th	Max
0-2	31	13.7	2.1	10.4	10.4	13.1	17.4	19.0

F. Glossary of Anatomical and Anthropometric Terms.

Technical terms which are used in the description of the particular measurements conducted in this study are defined below. Where possible, an attempt has also been made in the description of each measurement to use the most clearly understood term, and in some cases, provide both a technical and non-technical term so that both the professional anthropometrist and the untrained reader can clearly understand and reproduce the measurements.

1. Body Landmarks

ACROMION - The most lateral bony point on the acromion process of the scapula (shoulder blade). It is near the shoulder joint center of rotation.

AXILLA - The armpit.

CALF - The greatest muscular development of the lower leg formed by gastrocnemius and soleus muscles.

CLAVICLE - The "collar bone" which lies between the sternum and acromion process of the scapula.

CRINION - The point on the forehead where the hairline intersects the midline.

DIGIT - A finger or toe.

EXTERNAL CANTHUS - The most lateral outer angle of the slit between the eyelids.

GLABELLA - The most prominent point palpable on the forehead between the eyebrows (supra-orbital ridges) and above the junction of the nose (nasofrontal suture) with the forehead.

GLUTEAL FURROW - The crease at the junction of the back of the legs with buttocks.

GREATER TROCHANTER - The large bony prominence located on the lateral (outside) aspect of the shaft of the upper leg bone (femur). It is near the joint center of rotation for the hip.

ILIAC CREST - The palpable ridge along the upper and outer surface of the pelvis.

ILIOCRISTALE - The highest point on the lateral brim of the iliac crest of the pelvis.

ILIOSPINALE - The most forward point on the anterior-superior iliac spine of the pelvis.

MALLEOLI - The rounded bony prominence on either side of the ankle joint. The lateral malleolus is on the outside of the ankle (fibula) and the medial malleolus is the projection on the inside of the ankle (tibia).

MENTON - The bony point of the chin.

OPISTHOCRANION - The most posterior bony point from Glabella on the back of the head.

PATELLA - The kneecap.

PHALANGES - The long bones in the fingers.

RADIALE - A bony point at the uppermost point on the proximal border of the radius. It is found in the dimple on the lateral surface of the elbow with the arm hanging loose and palm forward. It is an approximation of the elbow joint center of rotation.

RADIUS - The bone on the thumb side of the forearm. It is the shorter of the two bones of the forearm.

RUMP - The buttocks in infants.

SELLION - The greatest nasal root depression at the junction of the nose with the forehead.

SOLE - The bottom of the foot.

SPHYRION - The most distal tip of the tibia below the medial malleolus at the ankle. It is an approximation of the ankle joint center of rotation.

STYLION - A bony point at the distal tip of the styloid process of the radius at the wrist. It can be palpated near the bony prominence on the thumb side of the wrist as the lower edge of the prominence closest to the hand. It is an approximation of the wrist joint center of rotation.

STYLOID PROCESS - The bony tip of either the radius or ulna at the wrist.

SUPRASTERNALE - The lowest, deepest point in the hollow of the notch of the manubrium (breastbone).

TIBIALE - The point at the upper inside edge on the head of the tibial bone of the lower leg. It is an approximation of the knee joint center of rotation.

TRAGION - The anterior portion of the cartilaginous notch just superior to the tragus (cartilaginous projection in front of ear hole) of the ear. The center of gravity of the head is located near an axis passing through the right and left tragion landmarks.

VERTEX - The highest point at the top of the head in the mid-sagittal plane.

ZYGOMATIC ARCH - The bony arch on either side of the face (cheekbone).

2. Body Orientations and Motions.

ABDUCT - To move away from the body in a lateral direction.

ANTERIOR - The front surface.

ANTERIOR-POSTERIOR - From front to back.

CENTER OF GRAVITY (C.G.) - That point in a body around which its weight is evenly distributed or balanced. In this study, center of gravity is reported as a lineal distance from a specified reference plane. It thus denotes the position of a plane through the body where the body could theoretically be balanced on a knife edge.

DISTAL - Farthest from the center (opposite to proximal).

EXTENSION - The straightening of one body segment relative to another.

FLEXION - The bending of one body segment relative to another.

FRANKFORT PLANE - The standard plane of orientation of the head, determined by locating the lowest point of the base of the bony margin of the left eye (orbitale) and the right and left ear holes (porion) in the same horizontal plane. This can be closely approximated when the subject looks directly forward.

INFERIOR - The lower surface, toward the feet.

MEDIOLATERAL - Relating to the middle and to a side.

MID-SAGITTAL PLANE - The front to back (anteroposterior) plane that pass approximately between the legs and through the middle of the body.

POSTERIOR - The back surface, toward the back or dorsal surface of the body.

SUPERIOR - The upper surface, toward the head.

CHAPTER IV

SUMMARY AND DISCUSSION

This report marks the completion of over five years of collecting anthropometric data on the current population of infants, children, and youth in the United States. In this study, data for 87 body measurements for 4127 children from age 2 weeks to 19 years have been collected, compiled, edited, statistically analyzed and presented in a format which can be utilized by all user groups. The previous Consumer Product Safety Commission sponsored measurement study included 4027 infants and children to age 12 for 41 body measurements. The combined studies result in a total of 93 functional and traditional body measurements taken on 8154 subjects throughout the United States. Together, these data represent the most comprehensive source of anthropometric information for application to child product safety currently available.

The critical need for child body size information was detailed in a previous survey compiled in 1972 of some 800 world-wide references (18). In this report an attempt has been made to present information that will correct the deficiencies observed in this survey of prior studies and to present the results in ways most useful to the potential user. However, anthropometry presents many complex relationships that may not be evident to the casual user. In this regard an attempt has been made to provide details of the problems encountered in data collection and analysis in Chapter II. This chapter will briefly discuss the results relative to further relationships and observations which are intended to assist the user in understanding the limits and meaning of the data presented.

A. Representativeness of Sample

A major goal of this study was to obtain anthropometric measurements on a sample of subjects which would be representative of the U.S. population. Racial, geographic, and socio-economic factors

were recorded and every attempt made to achieve a reasonable and representative balance of the factors that might bias the measurement statistics. A National Sampling Scheme was utilized for selecting schools and school districts in an attempt to provide a random sampling of children from rural and suburban areas.

Racial differences in man have been observed in body size and proportions as well as among ethnic groups of different national ancestry within a single race. With regard to race, the final sample was in excellent agreement with estimates from the U.S. Department of Health, Education and Welfare, National Center for Health Statistics, in that 11% was identified as black (Negroid), 1.0% Oriental (Mongoloid) including 0.1% American Indian, 86.5% as white (Caucasoid), and 1.5% as "Other", a category which included those individuals which were of unknown racial affiliation, usually a mixture. It should be pointed out, however, that since there is a lack of precise genealogical and biological information on each subject racial designations can only be approximate. Within the limitations presented by the HEW racial proportions, it is believed that this study is racially representative of the U. S. population.

Graphically, the sample was distributed throughout the conterminous United States, utilizing the National Sampling Scheme, which took into consideration census and demographic data. Since some regions chosen by this design could not be used, an attempt was made to substitute comparable alternate locations. The sample included both rural and urban populations as well as varied socio-economic factors. An attempt was made to cross-check pertinent criteria by periodic evaluation of the questionnaires, and observations by the measurers. However, the school locations within a particular city, town, or area were chosen to provide a sample with varied socio-economic backgrounds, and where particular schools selected by the national design could not be used, an effort was made to substitute a school within the area consisting of a similar socio-economic background. This involved assistance from the local school administrations, which often had very detailed breakdowns of

the makeup of each schools' population.

No matter how "good" or sophisticated a sampling design may be in theory, bias may occur in practice, particularly where subjects must volunteer. It was found, for example, that in junior high and high school, teenagers were more self conscious of physical characteristics, and that the athletic or more physically mature individuals may tend to participate more readily than lesser endowed individuals. While every attempt was made to discourage this type of bias (e.g., having schools offer academic credit incentive to students who participate) it is difficult to remove or measure all possible biases due to these factors.

B. Results with Respect to Age

Since it is common to think of children's physical dimensions as related to age, it is logical to present the data as a function of age. In both the previous study and this one, subject age was considered the primary independent variable for most of the data presentation. Measurement statistics calculated for subjects in selected age intervals and graphical displays were used with age as the horizontal axis (abscissa). Several points can be noted about the data presented in this way.

From the scatter plots and tabular data it is seen that the spread or variance of the measurements increase with age. This is as expected since the cumulative effects of varying growth rates become greater. It is also observed in many measurements, however, that the spread or variance increases more after age 14 for tables and plots where data for males and females are presented together. Again, this is expected and is due to the divergence in the measurements of the sexes. This can be observed on many of the scatter plots where until age 14 the females (x's) and males (+s) are jointly randomly distributed, and after age 14, the males tend to separate above the females. This is seen for both height and weight type measurements since in the teen years males tend to be both

taller and heavier than females. This is also quite apparent in many of the head, face and hand measurements where one might not expect such differences. For step height, the large variances relative to the measurement range reflect the fact that subject motivation and interpretation of instructions may also influence the results.

On the scatter plots of some measurements (e.g., wrist breadth, finger diameter), it will be noted that the points tend to cluster or stratify rather than be randomly distributed. There are two reasons for this. First, if the total range of the plot values is small as is the case for wrist breadth, the clustering is due to the fact that all measurement values have been rounded off to the nearest millimeter. For hand clearance and finger diameters the clustering is due to the fact that only discrete measurement values corresponding to the hole sizes in the measurement boards were recorded.

With regard to weight and other measurements related to weight such as waist circumference, it is also interesting to note that the bottom edge of the scatter plot is usually quite smooth while the top edge shows a wide scattering of data points. This scattering becomes most apparent above an age of about 8 and indicates the tendency for the population to be skewed toward heavier individuals. Another way of stating this is that there is an apparent minimum limit in body weight, but the maximum limit is indefinite. This skewness is not observed for stature or height measures where the measurements are primarily influenced by skeletal size.

Concerning center of gravity measurements, it was again observed that as a percent of stature, the center of gravity is nearly constant at 56-58 percent although a slight decrease from age 2 to 18 is seen. Seated center of gravity as a percent of sitting height decreases from about 35 percent at 2 years to 27 percent at 18 years while as a percent of buttock-knee length it is again nearly constant at about 42 percent.

C. Bivariate Measurement Relationships.

In the bivariate plots shown in Section D of Chapter III several

interesting points can be observed. In the weight versus stature scatter plot for 2-18 years, the non-linearity of the relationship is obvious. For persons of larger stature the relationship has a steeper slope than for persons of small stature. While these are cross-sectional data and not longitudinal growth data, the implication would seem to be that as a person gets closer to his mature stature his weight continues to increase due to growth in other directions or a filling out of body mass. At low statures corresponding to young children and for infants, the relationship is nearly linear, indicating that weight gain is a constant function of stature gain.

In other bivariate relationships, it will be noted that those length measurements plotted with stature are quite linear and the variance is nearly constant throughout the curve. Those plotted with weight, however, show a more curved relationship and an increasing variance with larger weights. It is also interesting to note the separation of the data points into two groups for some measurements like maximum hip breadth or maximum thigh breadth versus weight. From the regression coefficients for males and females it is seen that these groups correspond to changing relationships of the measurements between sexes. Females tend to have broader hips, for example, per given weight after 50 kg than males. This divergence of the sexes probably accounts for the increasing variance on the weight curves even when the separation is not apparent (e.g., shoulder breadth or thigh clearance with weight).

D. Use of Summary Statistics

In this study, as is traditionally done in anthropometric surveys, the summary statistics including mean, standard deviation, 5th, 50th, and 95th percentiles and minimum and maximum values have been given for each measurement and for various subject groupings by age and sex. In addition, every data point has been plotted in a measurement versus age scatter plot along with each table in order to indicate visually the relationship with age and the variability of the bandwidth.

With regard to the minimum and maximum values, it can be seen in scanning values for most measurements, that there are some minor fluctuations up and down as age increases. On the scatter plots one can observe the scattering of extreme data points from which these fluctuations result. In fact, if one were to shift the age groups one or two months either way, the pattern of minima and maxima would also shift. Thus, the minimum and maximum values shown are merely extremes of the particular sampled population and are subject to the limitations imposed by chance, sample size, and criteria for subject groups.

Engineers and product designers may find the 5th and 95th percentile values most useful, since it is these values which bracket the dimensions into which 90% of the population can be expected to lie. The user should be cautioned, however, in the use and limitations of percentiles to describe an individual or class of individuals. As Daniels (3) has demonstrated it is virtually impossible to find an individual who is "average" in more than a few body measurements. Similarly, no one person is 5th or 95th percentile in more than a few dimensions. Anthropometrically, while the human body is the same in qualitative appearance within the species, there are considerable differences in the quantitative measures of the body. In statistical terms, there are relatively few dimensions that are highly correlated ($r > .70$) which means that the system varies in dimensional description within the same body and population.

A good example of how the correlation coefficient between anthropometric dimensions affects the designs of a workspace is found in a two-part article by Moroney (8) and Smith (17). Thirteen dimensions traditionally used as the workspace anthropometry were selected to demonstrate the effect of designing a workspace for those individuals who were outside the 5th and 95th percentiles for these dimensions. If an individual had any measured dimension that was smaller than the 5th percentile or greater than the 95th percentile for any of the 13 dimensions, he or she was excluded from the population for

which the workspace was being designed. Of an original sample size of 1,547, 814, or 52.62%, were excluded.

All this is to say that one cannot define or construct a 5th or 95th percentile human by adding together all the 5th and 95th percentile dimensions. For example, one does not obtain a person of 5th percentile stature by adding together 5th percentile linkage lengths. Such a task is further complicated by the complexity of the human anthropometric system whose dynamic spatial geometry cannot be predicted easily from static dimensional anthropometry. For example, one cannot actually predict the functional reach of the forearm in the horizontal plane by adding together the lengths shoulder-elbow, elbow-wrist and hand length since these measurements do not consider the joint linkage systems involved.

E. Statistical Comparisons

As mentioned at the beginning of Chapter III, a statistical comparison (analysis of variance) between measurement means for selected core measurements from the three subsamples (i.e., three data sets) taken in this study showed no significant difference between these subsamples at the .05 level of significance. A similar comparison was made between results taken by automated and standard measurement techniques in this study and between results for this study and the previous CPSC study completed in 1975 by comparing selected core measurements.

Table 4 shows the results obtained by using a Student's t-test to compare means for selected core measurements taken by automated and standard techniques. As indicated in the last column there was a significant difference at the .05 level in several instances. If one excludes the first two age groups, however, it is observed that a statistically significant difference in the means occurred in only 6 out of 30 cases and that these were randomly distributed among the

Table 4. Statistical Comparisons of Selected Measurement Means for Automated Versus Standard Measuring

Age (Yrs)	Mean Value		Difference		Sig. Diff. @ .05 level

13-15	68.7	(91)	68.9	(466)	-.2	No
15-19	73.7	(169)	73.9	(531)	-.2	No

age groups and measurements. It is also observed, that while the differences were statistically different in these cases, the actual differences are probably not significant from a design point of view.

For the 2-4 and 4-6 year groups, the differences may be explained by differences in age distribution for the two techniques. As has been previously mentioned, standard techniques were used most often in day care centers where only a few children could be measured and physical conditions were not conducive to the computer system. Subjects measured at these facilities were generally in the range of 3 to 4 years old. Toddlers from 2-3 years were generally measured using the automated equipment while 5-6 year olds were usually measured in schools also using the automated equipment. Thus, in the age group 2-4, standard measuring accounts for most of the 3-4 year olds and automated measuring accounts for most of the 2-3 year olds. This accounts for the fact that the mean values for standard measuring are consistently larger than for automated measuring in this age group. Similarly, for 4-6 year olds, standard measuring accounts for most of the 4-5 year olds and automated for most of the 5-6 year olds resulting in the fact that the measurement means for standard measuring are almost always smaller than for automated measuring.

Other differences between results from the two techniques may also be explained by differences in sampling locations. For example, much of the standard measuring for subjects over 5 years was conducted in summer camps and seasonal effects on body dimensions may therefore be a factor.

It should also be pointed out, however, that some differences may be attributed to changes in the "feel" between the standard and automated instruments to the anthropometrist. As much as one would like to mechanize the anthropometric process, there remains a personal element and changes in instrumentation and anthropometrists can and will have an effect. In this study, one purpose of the automated equipment was to standardize and minimize those effects and every attempt was made to utilize this equipment at all times. While

certain practical constraints previously discussed necessitated the use of standard equipment at times, it can be seen from Table 4 that 70% of the subjects over 6 years were measured by automated equipment. Thus, differences caused by use of standard instrument techniques on the overall results are reduced by the relative sample sizes.

Table 5 shows the results obtained by using a Student's t-test to compare population means for selected measurements taken in the 1975 study with the same measurements taken in the present study. At first glance a number of cases where a statistically significant difference exists are observed. On closer inspection, however, it is seen that the actual differences are probably not functionally important from a design application viewpoint. Similar to the results for 2-4 and 4-6 year olds in Table 4, many of these differences may be attributed to differences of age distribution between the studies within the age groups compared. For example, for infants less than 6 months (.5 years), the 1975 study mean values are consistently smaller than the 1977 study mean values reflecting the fact that a larger number of the infants in the 1975 study were measured at infant clinics where most infants are less than 3 months. Similarly, the 1½-2 year olds show consistently larger mean values in the 1975 study reflecting differences in sampling and age distribution in the two studies. Two other factors which may be reflected in these statistical differences include differences in geographic distribution and differences in anthropometrists.

The fact that these differences appear to exist between two studies conducted under such similar circumstances only serves to point out the magnitude of the problem one has in combining or using anthropometric data taken in two or more independent studies. It does not alter the fact that the combined results of these two studies represent the most accurate, consistent, and complete body of U. S. infant, child and youth anthropometric data available today for application to consumer product design.

Table 5. Statistical Comparisons of Selected Measurement Means for 1975 and 1977 CPSC Child Measurement Studies

Age (Yrs)	Mean Value		Difference 1975-1977	Sig. Diff. @ .05 level

RELATED TECHNICAL REPORTS AND PUBLICATIONS

The following publications, reports, technical presentations, and films have resulted from this and the previous CPSC studies.

Publications

1976 INSTRUMENTATION FOR PEDIATRIC ANTHROPOMETRY, Owings, C.L., R.G. Snyder, and L.W. Schneider, Proceedings, American Academy of Medical Instruments, Atlanta, Ga. 21 March.

1975 Snyder, R.G., C.Owings, M. Spencer, and L.W. Schneider, NEW TECHNIQUES FOR INFANT AND CHILD ANTHROPOMETRY: MINI-COMPUTER CONTROLLED ANTHROPOMETRY AND CENTER OF GRAVITY MEASUREMENTS (LA ANTROPOMETRIA Y LAS MEDIDAS DEL CENTRO DE GRAVEDAD DE LOS NINOS ESTADOUO INDENSES UTILIZANDO EL AVANZADO SISTEMA AUTOMATIZADO DE MICHIGAN DE LA MINI-CALCULADORA ELECTRONICA) Proceedings, American Anthropological Association, p. 133, Mexico City (November)

Owings, C.L. L.W. Schneider, R.G. Snyder, and M.L. Spencer, A PORTABLE SYSTEM FOR INFANT AND CHILD CENTER OF GRAVITY MEASUREMENT. Proceedings, Conference on Engineering, Medicine and Biology, Pg. 375, (October).

Owings, C.L., L.W. Schneider, R.G. Snyder, and M.L. Spencer, COMPUTER CONTROLLED ANTHROPOMETRY: A PORTABLE SYSTEM FOR USE WITH INFANTS AND CHILDREN, Proceedings, Conference on Engineering, Medicine and Biology, p. 385, (October).

Snyder, R.G., M.L. Spencer, C.L. Owings, and L.W. Schneider, INFANTS AND CHILDREN ANTHROPOMETRY (L'ANTHROPOMETRIE DES ENFANTS ET DES NOURRISSIONS) Proceedings, International Research Committee on Biokinetics of Impacts, Biomechanics of Trauma in Children. Pg. 139-149. Lyon, France (September).

Owings, C.L., R.G. Snyder, M.L. Spencer, and L.W. Schneider, NEW TECHNIQUES FOR INFANT AND CHILD ANTHROPOMETRY: MINI-COMPUTER CONTROLLED ANTHROPOMETRY AND CENTER OF GRAVITY MEASUREMENTS, Proceedings, American J. of Physical Anthropology, (February)

1972 Snyder, R.G., M.Spencer, C. Owings, and P. Van Eck, SOURCE DATA OF INFANT AND CHILD MEASUREMENT, Interim Data, 1972. Prepared for U.S. Food and Drug Administration, Children's Hazards Division Bureau of Product Safety, Bethesda, Maryland, by the University of Michigan, Ann Arbor, December.

Snyder, R.G., M. Spencer, and C. Owings, SELECTED INFANT ANTHROPOMETRY CRIB SLAT STUDY, Food and Drug Administration, Bureau of Product Safety, Children's Hazards Division, Bethesda, Md., Report, 18 December.

Oral Presentations

1975 NEW WAYS TO MEASURE CHILDREN: IMPLICATIONS FOR SAFETY. R.G. Snyder and C.L. Owings, University of Michigan Science Research Symposium The Chrysler Center.

1975 SAE Engineering Congress, Detroit, 28 February. Snyder, R.G. C. Owings, M. Spencer, L. W. Schneider, and H. Reynolds, ANTHROPOMETRY OF U.S. CHILDREN.

1974 27th Annual Conference on Engineering in Medicine and Biology, Phila., 6 October 1974. Owings, C.L., L.W. Schneider, R.G. Snyder and M.L. Spencer. A PORTABLE SYSTEM FOR INFANT AND CHILD CENTER OF GRAVITY MEASUREMENT.

27th Annual Conference on Engineering in Medicine and Biology, Phila. 6 October 1974. COMPUTER CONTROLLED ANTHROPOMETRY: A PORTABLE SYSTEM FOR USE WITH INFANTS AND CHILDREN. Owings, C. L., L. W. Schneider, R.G. Snyder, and M. L. Spencer.

American Anthropological Association, Mexico City, Mexico, 20 November 1974. Snyder, R.G., C.L. Owings, M. L. Spencer and L.W. Schneider, NEW TECHNIQUES FOR INFANT AND CHILD ANTHROPOMETRY: MINI-COMPUTER CONTROLLED ANTHROPOMETRY AND CENTER OF GRAVITY MEASUREMENTS.

International Research Committee on Biokinetics of Impacts, Biomechanics of Trauma in Children, Lyon, France, 18 September 1974. Snyder, R.G., M.L. Spencer, C.L. Owings, and L.W. Schneider, INFANT AND CHILD ANTHROPOMETRY.

Annual Meeting, American Association of Physical Anthropologists, University of Massachusetts, Amherst, 11 April. Owings, C.L., R.G. Snyder, M. Spencer, and L.W. Schneider, NEW TECHNIQUES FOR INFANT AND CHILD ANTHROPOMETRY: MINI-COMPUTER CONTROLLED ANTHROPOMETRY AND CENTER OF GRAVITY MEASUREMENTS.

Films

1975 NEW METHODS OF INFANT AND CHILD ANTHROPOMETRY FOR PRODUCT SAFETY. 18 minutes-color-sound-16mm. 31 March.

1973 CRIB-SLAT STUDY. TV release. 1 min. 30 sec.-color-sound-16mm-24 July.

Automatic Data Processing

1977 Consumer Product Safety Commission Final Summary data in both printed tabular format and IBM compatible magnetic tape (9-track 1600 BPI with standard label) for 87 measurements of 4,127 U.S. children from age 2 weeks through 18 years. (31 April).

1975 Consumer Product Safety Commission Final Summary data in both printed tabular format and IBM compatible Magnetic Tape (9-track

1600 BPI with standard label) for 41 measurements of 4027 U.S. children from age 2 weeks to 12 years. (31 March).

In Preparation

ORBITAL DIMENSIONS OF CHILDREN AGED 2 THROUGH 12 YEARS, Snyder, R.G., C.L. Owings, L.W. Schneider, and M. Spencer.
