where \( k_{D,eq} \equiv -\langle \rho | L | \rho \rangle \) is the so-called "equilibrium dissociation rate coefficient," then it is easily shown that the moments \( N_\mu = \langle \langle 1 | \Psi | \chi_\mu \rangle \rangle \) of the eigenvectors \( | \chi_\mu \rangle \) are of the order of magnitude

\[
N_\mu = 1 + O(e^\mu), \quad N_\mu = O(\mu) \quad \text{for} \quad \mu > 0. \tag{3}
\]

Singular perturbation methods may then be used to obtain a uniformly valid asymptotic solution for \( | X(t) \rangle \). The result shows that after a short initial transient the dissociation and recombinaton rate coefficients, \( k_D \) and \( k_R \), approach the "steady-state" value

\[
k_D = K_{eq} k_R = \lambda_0 \left[ 1 + 8(1-N_0)K_{eq}^{-1}N_A + O(e^\mu) \right], \tag{4}
\]

where \( K_{eq} \) is the dissociation equilibrium constant. Since this expression depends only on \( \lambda_0 \) and \( | \chi_0 \rangle \), and since for a given set of initial conditions the incubation time caused by the initial transient may be shown to depend only on \( | \chi_0 \rangle \), we see that all the important parameters describing the dissociation and recombination of diatomic molecules may be determined from the lowest eigenvalue and the corresponding eigenvector. This fact is of immense importance for both analytical and numerical calculations of the rate coefficients and incubation times because, in the limit indicated by Eq. (2), the lowest eigenvalue and the corresponding eigenvector are easily approximated by rapidly convergent iterative techniques.

To show how this may be done, we express the eigenvalue equation (2) in the form \( | X_0 \rangle = -\lambda_0 L^{-1} \Psi | X_0 \rangle \). If we substitute a trial vector for \( | X_0 \rangle \) in the right-hand side of this equation and perform the indicated operation, we obtain a first approximation to the eigenvector \( | X_0 \rangle \), within a normalization constant. This first approximation may, in turn, be used as a trial vector to get a second approximation, and so on. After sufficient iterations, the result converges to \( | \chi_0 \rangle \) with any desired degree of accuracy, in the sense of mean-square error, provided only that the initial trial vector is not orthogonal to \( | \chi_0 \rangle \). To prove this, we define the \( n \)th approximation to the unnormalized eigenvector by the formula \( | f^{(n)} \rangle = -L^{-1} \Psi | f^{(n-1)} \rangle \). Then, since the initial trial vector \( | f^{(0)} \rangle \) may be expressed in terms of the eigenvectors \( | \chi_\mu \rangle \) by means of the expansion \( | f^{(0)} \rangle = \sum b_\mu | \chi_\mu \rangle \), we find that the mean-square error in the normalized eigenvector is

\[
E^{(n)} = 2 - 2\langle f^{(n)} | \Psi | \chi_\mu \rangle / \langle f^{(n)} | \Psi | f^{(n)} \rangle^{1/2} \sim \sum_{\mu > 0} (b_\mu^2 \lambda_\mu^{2n} / b_\mu^2 \lambda_\mu^{2n-1}), \tag{5}
\]

which vanishes as \( n \to \infty \) provided that \( b_\mu \neq 0 \). A simple approximation to the eigenvalue \( \lambda_0 \) may be obtained from the formula

\[
\lambda^{(n)} = \langle f^{(n)} | \Psi | f^{(n-1)} \rangle / \langle f^{(n)} | \Psi | f^{(n)} \rangle \sim \lambda_0 [1 + \sum_{\mu > 0} (b_\mu^2 \lambda_\mu^{2n-1} / b_\mu^2 \lambda_\mu^{2n-1})] \tag{6}
\]

which approaches \( \lambda_0 \) as \( n \to \infty \) provided that \( b_\mu \neq 0 \).

In the limit indicated by Eq. (2) the calculation converges very rapidly, and only one iteration is necessary. For our initial trial vector we choose the equilibrium distribution \( | f^{(0)} \rangle = | 1 \rangle \). In practice, this usually deviates significantly from \( | \chi_0 \rangle \) only in the upper energy levels where the weighting function \( \psi_i \) is small. The expansion coefficients \( c_i \) are given by the formula \( \langle f^{(0)} | \Psi | \chi_\mu \rangle = N_\mu \). The first approximation to \( \lambda_0 \) is therefore

\[
\lambda^{(0)} = -\langle 1 | \Psi L^{-1} \Psi | 1 \rangle / \langle 1 | \Psi L^{-1} \Psi L^{-1} \Psi | 1 \rangle \sim \lambda_0 [1 + O(\mu)], \tag{7}
\]

where the asymptotic limit follows from Eq. (3). The first approximation to \( | \chi_0 \rangle \) is

\[
| \chi^{(0)} \rangle = -L^{-1} \Psi | 1 \rangle / \langle 1 | \Psi L^{-1} \Psi L^{-1} \Psi | 1 \rangle^{1/2}, \tag{8}
\]

which, in view of Eq. (3), has a mean-square error \( E^{(0)} = O(\mu) \). Of course, the relative error in the second-order quantity \( (1-N_0) \) is somewhat larger. Nevertheless, we readily find that \( (1-N^{(0)}) = (1-N_0)[1+O(\mu)] \), which is consistent with the accuracy of Eq. (4).

Ground-State Wavefunctions and Energies for the Helium Isoelectronic Series through \( Z = 10^* \)

ROBERT T. BROWN

(Received 16 June 1967)

The method of configuration interaction with a truncated complete set of functions and one variable scale parameter which was recently applied to the first four members of the helium isoelectronic series has been extended to this series through \( Z = 10 \). The energies obtained for \( Z \geq 5 \) are lower than have previously been obtained with a configuration-interaction approach, and differ from those obtained with Hylleraas-type functions by 0.002% for \( Z = 5 \) and by 0.0007% for \( Z = 10 \). It is found that for \( Z \geq 2 \) there is a finite range of values of the scale parameter near the energy minimum over which the energy varies by less than 0.00001 a.u., which is the limit of the precision used in the matrix diagonalization.
energy minimum was studied by calculating the expectation value for which there is no significant change in the energy. The maximum and minimum values obtained are shown in Table II, and compared with the sixth-order perturbation calculation of Scherr and Knight. This expectation value was chosen for several reasons. It is the one property, other than the energy, of an atom in a $1S$ state which can be obtained directly from the wavefunction and which can be related to an experimentally measured quantity, in this case the magnetic susceptibility. It has been calculated for $Z=2$ by many different methods, not all of which are based on the energy criterion. A comparison with these other calculations as well as with the experimental value is shown in Table III. Finally, the dominant contribution to this expectation value comes from a significantly different region in space than that which furnishes the dominant contribution to the energy. The agreement shown in Tables II and III provides assurance that the minimum energy is not being obtained at the expense of the spatial behavior of the trial function, and in fact is somewhat better than might be expected from a wavefunction which gives the energy to four or five significant figures. Because of this it seems likely that this type of wavefunction should be quite useful for calculating transition probabilities and other properties of these ions obtainable from oscillator strengths, and this work is now in progress.

### Table I. Ground-state energies for the helium isoelectronic series (in atomic units).

In Table I are shown the results obtained with the 120-term expansion

$$\Psi_{12} = \sum_{n=1}^{8} \sum_{l=0}^{n-1} \sum_{k=0}^{l} C(n_1, n_2, l) \phi_{12}(n_1, n_2, l),$$

in which each configuration is the appropriate antisymmetrized combination of products of the numerably complete set of single-particle functions,

$$\psi_{nlm}(\xi, \theta, \phi) = \frac{[\Gamma(n-l)]^{1/2}}{[\Gamma(n+l+1)]^{1/2}} \times \exp(-\xi/2) L_{n-l} e^{i2\pi l}(\xi) Y_l^m(\theta, \phi),$$

of the scaled variable $\xi = 2kr$. The two values of the scale parameter $k$ shown in Table I are the limits of the range of $k$ over which the energy varies by less than 0.00001 a.u.

Since it is the wavefunction, or the approximate solution to the Schrödinger equation, which is ultimately of interest, the behavior of the wavefunction near the energy minimum was studied by calculating the expectation value $\langle \rho^2 \rangle = \frac{1}{2} \langle (r_1^2 + r_2^2) \rangle$ over the range of scale parameter for which there is no significant change in the expectation value $\langle \rho^2 \rangle$ for two-electron atoms (atomic units).
