ABSTRACT

A number of trajectory planning algorithms are available for determining a time history of the joint torques, positions, and velocities required to move a manipulator along a given geometric path in minimum time. These schemes require knowledge of the robot's dynamics, which in turn depend upon the characteristics of the payload which the robot is carrying. In practice, the dynamic properties of the payload will not be known exactly, so that the dynamics of the robot, and hence the required joint torques, must be calculated for a nominal set of payload characteristics. But since these trajectory planners generate nominal joint torques which are at the limits of the robot's capabilities, moving the robot along the desired geometric path at speeds calculated for the nominal payload may require torques which exceed the robot's capabilities. In this paper, bounds on joint torque uncertainties are derived in terms of payload uncertainties. This allows the trajectory planner to incorporate payload uncertainties into the trajectory planning process.
1. INTRODUCTION

Various algorithms are available for performing trajectory planning for robots, i.e., generating a time history of desired positions, velocities, accelerations and torques [1, 5, 6]. These trajectory planners require knowledge of the robot's dynamics, which in turn depend upon the characteristics of the payload being carried. In practice, the exact characteristics of the payload will not be known; since the trajectory planners referenced above need to know the exact dynamics of the robot, the trajectory planning process must be carried out with dynamics which are calculated for a nominal payload. This practice can lead to difficulties. To see why this is the case, note that these trajectory planners generate nominal torques which are at the limits of the robot's capabilities for the given dynamics. Moving the robot along the desired path at speeds calculated for the nominal payload may therefore require torques which are beyond the robot's capabilities if the payload differs from the nominal one. If the robot's joints are controlled by independent servoes, as is usually the case, then attempting to make the robot move along the nominal trajectory will result in one or more joints "falling behind", so that the robot strays from the desired geometric path. In other words, the trajectory generated by the trajectory planner is realizable for the nominal payload, but not for the actual payload.

There are a number of adaptive controllers which can compensate for the changes in load, provided that the plant (i.e. the robot joint drive) does not saturate [3, 2]. However if the plant saturates, as may happen if the actual and nominal payloads differ too much, then these controllers cannot possibly compensate for load changes. It is the objective of this paper to present an analysis of the torque errors caused by
payload changes, and incorporate the error information into the trajectory planning process so as to avoid saturation of the individual actuators.

Changes in payload characteristics will be expressed as errors in the \textit{pseudo-inertia} of the payload; the pseudo-inertia is a matrix containing the mass and first and second moments of the payload. It will be shown that bounds on the joint torque errors can be calculated in terms of the norm of the error in the pseudo-inertia of the payload, given the robot's kinematics. The general trajectory planning algorithm given in [6] can then be modified to handle uncertainties in the dynamics caused by the payload. If the actual and nominal payloads are described by the pseudo-inertias $I_A$ and $I_N$ respectively, then for a given positive real number $E$, the algorithm generates a trajectory which is realizable for all payloads $I_A$ for which $||I_A - I_N|| \leq E$.

In order to determine errors in the torques, the dynamic equations of the robot are required. In tensor notation, the dynamic equations describing the behavior of a robot take the general form

$$ u_i = J_{ij} \ddot{q}^j + C_{ijk} \dot{q}^j \dot{q}^k + R_{ij} \dot{q}^j + g_i \quad (1.1) $$

where $u_i$ is the \textit{i}th generalized force, $q^i$ is the \textit{i}th generalized coordinate, $J_{ij}$ is the inertia matrix, $C_{ijk}$ is an array of Coriolis coefficients, defined by

$$ C_{ijk} = \frac{1}{2} \left( \frac{\partial J_{ij}}{\partial q^k} + \frac{\partial J_{ik}}{\partial q^j} - \frac{\partial J_{jk}}{\partial q^i} \right) \quad (1.2) $$

The matrix $R_{ij}$ is the viscous friction matrix, and $g_i$ is the gravitational force. The summation convention has been used here, so that all product terms in (1.1) are summed from 1 to $N$ over repeated indices, where $N$ is the number of degrees of freedom of the robot. The inertia matrix $J_{ij}$, the Coriolis array $C_{ijk}$ and the gravitational
loading vector \( \mathbf{g}_i \) are all functions of the position of the robot and the payload pseudo-inertia.

It will be assumed that the path which the robot is expected to follow has been given as a parameterized curve in joint space, i.e., the joint coordinates \( q^i \) are given in terms of a single scalar \( \lambda \) by the equations

\[
q^i = f^i(\lambda), \quad 0 \leq \lambda \leq \lambda_{\text{max}}.
\]

This allows all of the joint positions, velocities, and accelerations to be expressed in terms of the scalar parameter \( \lambda \) and its time derivatives. Plugging these relations into the dynamic equations gives torque in terms of these quantities also. More specifically, we have

\[
u_i = \mathbf{J}_{ij} \frac{df^i}{d\lambda} \mu + \left\{ \mathbf{J}_{ij} \frac{d^2f^i}{d\lambda^2} + \mathbf{C}_{ijk} \frac{df^i}{d\lambda} \frac{df^k}{d\lambda} \right\} \mu^2 + \mathbf{R}_{ij} \frac{df^i}{d\lambda} \mu + \mathbf{g}_i \]

where \( \mu \equiv \dot{\lambda} \) is the \textit{pseudo-velocity}. The quantities \( \mathbf{J}_{ij}, \mathbf{C}_{ijk}, \) and \( \mathbf{g}_i \) depend upon the masses and moments of inertia of the robot's links. The robot's payload is fixed to the last link, and hence must be regarded as part of the last link for purposes of calculating the dynamic coefficients. Therefore \( \mathbf{J}_{ij}, \mathbf{C}_{ijk}, \) and \( \mathbf{g}_i \) will change as the characteristics of the payload vary.

We may write Eq. (1.4) as

\[
u_i = M_i(\lambda, I_N)\dot{\mu} + Q_i(\lambda, I_N)\mu^2 + R_i(\lambda)\mu + S_i(\lambda, I_N)
\]

where the coefficients \( M_i, Q_i, R_i, \) and \( S_i \) are given by

\[M_i \equiv \mathbf{J}_{ij}(I_N) \frac{df^i}{d\lambda}\]
\[ Q_i = J_{ij}(I_N) \frac{d^2 f^j}{d \lambda^2} + C_{ijk}(I_N) \frac{df^j}{d \lambda} \frac{df^k}{d \lambda} \]

\[ R_i = R_{ij} \frac{df^j}{d \lambda} \]

and

\[ S_i = g_i(I_N). \]

The functional dependence of \( J_{ij}, C_{ijk} \) and \( g_i \) on the payload \( I_N \) has been shown explicitly. Then the dynamics of the system after the payload has been perturbed may be written

\[ u'_{ij} = M_i(\lambda, I_N + \Delta I_N) \dot{\mu} + Q_i(\lambda, I_N + \Delta I_N) \mu^2 + R_i(\lambda) \mu + S_i(\lambda, I_N + \Delta I_N). \]  

(1.6)

In order to avoid excessive torque requirements, we wish to compute a set of velocities and accelerations \( \mu \) and \( \dot{\mu} \) such that if the nominal torques \( u_i \) are given by (1.5), then the actual torques \( u'_{ij} \) given by (1.6) will be realizable, i.e.,

\[ u_{i_{\text{min}}}(\lambda, \mu) \leq u'_{ij} \leq u_{i_{\text{max}}}(\lambda, \mu). \]  

(1.7)

Formally, the Robust Trajectory Planning (RTP) problem may be stated as follows:

Given a geometric path described as a parameterized curve, the torque limits \( u_{i_{\text{min}}} \) and \( u_{i_{\text{max}}} \) as functions of \( \lambda \) and \( \mu \), the dynamics of the robot when carrying the nominal payload \( I_N \), and a bound \( E \) on the norm of the difference between the pseudo-inertias of the actual and nominal payloads, determine the fastest trajectory (sequence of \( (\lambda, \mu) \) pairs) such that the torques \( u'_{ij} \) given by (1.6) satisfy the constraints (1.7) for all points on the trajectory and for all payload errors \( \Delta I_N \) such that \( ||\Delta I_N|| \leq E \).

We will solve this problem by calculating the worst-case torque error, as a function of \( \lambda \), \( \mu \), and \( \dot{\mu} \), for a given payload error, and decreasing the torque limits by this amount when doing trajectory planning.
The rest of the paper is organized as follows: in Section 2, torque errors are calculated in terms of changes to the payload pseudo-inertia. In Section 3, bounds on the joint torque errors are derived in terms of bounds on the norm of the pseudo-inertia error. Section 3 also discusses how these results can be incorporated into the trajectory planning process. Section 4 presents a numerical example, and the paper concludes with Section 5.

2. CALCULATION OF DYNAMIC COEFFICIENT ERRORS

For a given path, we need to know the changes to the coefficients $M_i$, $Q_i$, $R_i$, and $S_i$ in Eq. (1.5) which result from changes in the dynamics of the robot. In the sequel, changes in dynamics will be assumed to come from changes in payload characteristics. While changes in friction coefficients, and hence changes to $R_i$, also contribute to changes in required torques, such changes are independent of changes in payload characteristics, and for the sake of simplicity will not be dealt with here.\(^1\)

Determining the change to $M_i$, we have

$$M_i(I_N) = J_{ij}(I_N) \frac{df_j}{d\lambda}$$

(2.1)

and

$$M_i(I_N + \Delta I_N) = J_{ij}(I_N + \Delta I_N) \frac{df_j}{d\lambda}$$

(2.2)

so that

$$\delta M_i(I_N, \Delta I_N) \equiv M_i(I_N + \Delta I_N) - M_i(I_N)$$

(2.3)

---

\(^1\)Such changes are usually determined experimentally.
\[ \begin{aligned}
&= \left\{ J_{ij}(I_N + \Delta I_N) - J_{ij}(I_N) \right\} \frac{df_i}{d\lambda} \\
&= \delta J_{ij}(I_N, \Delta I_N) \frac{df_i}{d\lambda}.
\end{aligned} \]

Differences between nominal and actual payload characteristics cause changes in the coefficients \( J_{ij}, C_{ijk}, \) and \( g_i \) in equation (1.1). Here we determine the relationship between changes in these coefficients and changes in payload characteristics.

Changes in payload characteristics will result in changes to the pseudo-inertia tensor of the last joint of the robot, i.e., the pseudo-inertia tensor will have the value \( I_N + \Delta I_N \) instead of \( I_N \). In order to obtain \( \delta M_i \), we consider how this affects the inertia matrix. The coefficients in the inertia matrix are given in [4] as

\[ J_{ij}(I_N) = \sum_{p = \max(i,j)}^{N} \text{Tr} \left( \frac{\partial T_p}{\partial q_i} I_p \frac{\partial T_p^T}{\partial q_j} \right) \tag{2.4} \]

where \( T_p \) is the 4\( \times \)4 homogeneous transformation matrix which transforms vectors given in the coordinate system associated with the \( p^{th} \) link of the robot to world or base coordinates, and \( I_p \) is the pseudo-inertia of the \( p^{th} \) link given in the \( p^{th} \) link's coordinate frame. The pseudo-inertia is defined as the matrix [4]

\[ I_p = \begin{bmatrix}
\int z^2 \, dm & \int xy \, dm & \int xz \, dm & \int z \, dm \\
\int xy \, dm & \int y^2 \, dm & \int yz \, dm & \int y \, dm \\
\int xz \, dm & \int yz \, dm & \int z^2 \, dm & \int z \, dm \\
\int z \, dm & \int y \, dm & \int z \, dm & \int dm
\end{bmatrix} \tag{2.5} \]

The coordinates \( z, y, \) and \( z \) are expressed in the \( p^{th} \) coordinate frame, and the integrals are all taken over the \( p^{th} \) link.
Introducing an error $\Delta I_N$ into the pseudo-inertia of the last joint gives

$$J_{ij}(I_N + \Delta I_N) = \sum_{p=\max(i,j)}^{N-1} \frac{\partial T_p}{\partial q^i} I_p \frac{\partial T_p}{\partial q^j} + \frac{\partial T_N}{\partial q^i} \frac{\partial T_N}{\partial q^j}.$$ \hfill (2.6)

Subtracting (2.4) from (2.6) gives

$$\delta J_{ij}(I_N, \Delta I_N) = \delta J_{ij}(\Delta I_N) = Tr \left( \frac{\partial T_N}{\partial q^i} \Delta I_N \frac{\partial T_N}{\partial q^j} \right).$$ \hfill (2.7)

Note that the error in the inertia matrix is linear in the pseudo-inertia error, and is independent of the nominal payload. To find $\delta M_i$, simply plug (2.7) into (2.3), giving

$$\delta M_i = \sum_{j} \frac{df^j}{d\lambda} Tr \left( \frac{\partial T_N}{\partial q^i} \Delta I_N \frac{\partial T_N}{\partial q^j} \right).$$ \hfill (2.8)

Computation of the errors $\delta Q_i$ follows the same pattern as the computation of $\delta M_i$. The errors in the Coriolis terms can be determined in much the same way as the errors in the inertia matrix. From [4] we have

$$C_{ijk} = \sum_{p=\max(i,j,k)}^{N} \frac{\partial^2 T_p}{\partial q^i \partial q^k} I_p \frac{\partial T_p}{\partial q^j}.$$ \hfill (2.9)

The errors in the Coriolis terms due to errors in payload characteristics are therefore given by

$$\delta C_{ijk} = Tr \left( \frac{\partial^2 T_N}{\partial q^i \partial q^k} \Delta I_N \frac{\partial T_N}{\partial q^j} \right).$$ \hfill (2.10)

The definition of $Q_i$ gives
\[ \delta Q_i = \sum_j \text{Tr}\left( \frac{\partial T_N}{\partial q^j} \Delta I_N \frac{\partial T_N}{\partial q^j} \right) \frac{d^2 f_i}{d \lambda^2} \]

\[ + \sum_i \sum_k \text{Tr}\left( \frac{\partial^2 T_N}{\partial q^i \partial q^k} \Delta I_N \frac{\partial T_N}{\partial q^i} \right) \frac{df_i}{d \lambda} \frac{df_k}{d \lambda}. \]  

Now we need to know the error in the gravitational terms. The gravitational forces \( g_i \) are given by [4]

\[ g_i = \sum_{k=i}^N m_k G^T \frac{\partial T_k}{\partial q^i} \bar{r}_k \]  

where

\[ G = \begin{bmatrix} 0 \\ 0 \\ g \\ 0 \end{bmatrix} \]

is the gravitational force vector, \( m_k \) is the mass of the \( k^{th} \) link, \( g \) is the acceleration due to gravity, and

\[ \bar{r}_k = \begin{bmatrix} \bar{x} \\ \bar{y} \\ \bar{z} \\ 1 \end{bmatrix} \]

is the center of mass of the \( k^{th} \) link given in the coordinates of the \( k^{th} \) frame. If we define \( w_k = m_k \bar{r}_k \), then we have

\[ g_i = -\sum_{k=i}^N G^T \frac{\partial T_k}{\partial q^i} w_k. \]
But $w_k$ is just the last column of the pseudo-inertia matrix $I_k$, so that

$$g_i = - \sum_{k=i}^{N} G^T \frac{\partial T_k}{\partial q^i} I_k \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}. \quad (2.14)$$

As before, introducing an error into the pseudo-inertia of the last link gives

$$\delta S_i = \delta g_i = -G^T \frac{\partial T_N}{\partial q^i} \Delta I_N \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}. \quad (2.15)$$

We may now calculate the error in $u_i$ by adding up the individual components, giving

$$\delta u_i = \delta M_i \dot{\mu} + \delta Q_i \mu^2 + \delta S_i. \quad (2.16)$$

3. CALCULATION OF TORQUE ERROR BOUNDS

If the errors $\Delta I_N$ were known exactly, then the torque errors could also be computed exactly. Of course, in practice $\Delta I_N$ will not be known exactly. However, if bounds on the norm of $\Delta I_N$ can be obtained, then we may find bounds on $\delta u_i$.

To obtain these bounds, note that $\delta M_i$, $\delta Q_i$, and $\delta S_i$ are all functions of the pseudo-inertia error $\Delta I_N$; in fact, they are linear in $\Delta I_N$, so that $\delta u_i$ is also linear in $\Delta I_N$. If we write

$$\delta u_i = Z(\Delta I_N), \quad (3.1)$$

then we wish to maximize or minimize the linear function $Z$ with respect to $\Delta I_N$, subject to
\[ \| \Delta I_N \| \leq E \] (3.2)

where \( E \) is the bound on the pseudo-inertia error.

At this point, some observations are in order. First, as we noted before, the errors in the \( \delta u_i \) depend linearly upon the pseudo-inertia error \( \Delta I_N \). Second, note also that \( \delta u_i \) depends only on the kinematics of the robot and on the desired velocity and acceleration, not on the nominal dynamics. These facts are consequences of the fact that both kinetic and potential energy are linear in mass. To see this, consider the form of the Lagrangian, namely \( L = K - P \), where \( K \) and \( P \) are the kinetic and potential energies of the robot. Any difference between the actual and nominal dynamics of the robot will cause a corresponding difference in the Lagrangian. If we think of the error in the pseudo-inertia as a piece of stray material stuck to the end effector, then both the kinetic and potential energies of this material, and therefore the Lagrangian, depend only upon the mass and shape of the stray material and upon the position and speed of the end effector. The Lagrangian is linear in the mass of the material; since Lagrange’s differential equations are linear in \( L \), the errors in the generalized forces can be separated from the forces resulting from the nominal mass of the manipulator. One consequence of this separability of forces is that the errors \( \delta u_i \) do not depend upon the nominal dynamics, as shown above. The implication of this is that much of the error analysis can proceed without regard to the nominal dynamics of the robot.

The linearity of the \( \delta u_i \) in the pseudo-inertia has some other practical consequences as well. Consider the maximization which must be performed in order to evaluate \( \delta u_i \). This maximization requires that the space of \( 4 \times 4 \) symmetric matrices with norm less than \( E \) be searched, which in general is a rather formidable problem.
However, by choosing a particular class of matrix norms, the problem can be made quite simple; in fact, it can be transformed into a linear programming problem.

To see how this transformation can be performed, consider the problem of maximizing the function $Z$ in equation (3.1), namely

\[
\text{Problem A: maximize } Z(M) = \sum_i \sum_j \beta_{ij} M_{ij} \tag{3.3}
\]

subject to $||M|| \leq E$ and $M=M^T$. \tag{3.4}

Treatment of the minimization problem proceeds analogously to problem A. We will show that problem A transforms into a linear programming problem if the norm used to constrain the matrix $M$ in (3.4) is chosen properly. This will be accomplished by eliminating some absolute values from the constraints.

$Z(M)$, the function to be maximized, is a linear function of $M$. It remains to be shown that the constraints can be made linear. Of course if the norm used in problem A is arbitrary, then in general the constraints will not be linear. However, there is a set of norms, all very easy to calculate, which will yield linear constraints. Consider the class of functions $F: R^{4 \times 4} \rightarrow R^+$ given by

\[
F(M) = \max_i \sigma_i(M)
\]

where

\[
\sigma_i(M) = \sum_{j=1}^{4} \sum_{k=1}^{4} \alpha_{ijk} |M_{jk}|.
\]

The matrix 1-norm and $\infty$-norm, $\max_{i,j} |M_{ij}|$ and $\sum_{i,j} |M_{ij}|$ are all functions of this
form. We now show that, under suitable conditions, $F$ is a norm.

Lemma: If $\alpha_{ijk} \geq 0$ for all $i$, $j$ and $k$, and if for every pair of indices $(j,k)$ there is an $i$ such that $\alpha_{ijk} \neq 0$, then $F(M)$ is a norm.

Proof: In order to prove that $F$ is a norm, we must show that

1) $F(M) \geq 0$ for all $M$,

2) $F(M) = 0$ iff $M = 0$,

3) $F(\gamma M) = |\gamma| F(M)$ for all scalars $\gamma$ and all matrices $M$, and

4) $F(X + Y) \leq F(X) + F(Y)$ for all matrices $X$ and $Y$.

Obviously (1) is true, since $F$ is the maximum of a set of non-negative quantities. $F(0) = 0$, proving the "if" part of (2). To prove the "only if" part, observe that if $M$ is non-zero, then it has some non-zero element $M_{jk}$. For this particular $jk$ pair, there is some $i$ such that $\alpha_{ijk}$ is non-zero, so that $\sigma_i > 0$ for this $i$. Therefore $F > 0$. (3) is true, since

$$\sigma_i(\gamma M) = \sum_{j=1}^{4} \sum_{k=1}^{4} \alpha_{ijk} |\gamma M_{jk}| = |\gamma| \sum_{j=1}^{4} \sum_{k=1}^{4} \alpha_{ijk} |M_{jk}| = |\gamma| \sigma_i(M)$$

and hence

$$F(\gamma M) = \max_i \sigma_i(\gamma M) = \max_i |\gamma| \sigma_i(M) = |\gamma| \max_i \sigma_i(M) = |\gamma| F(M).$$

Finally,

$$\sigma_i(X + Y) = \sum_j \sum_k \alpha_{ijk} |X_{jk} + Y_{jk}|$$

$$\leq \sum_j \sum_k \alpha_{ijk} |X_{jk}| + \sum_j \sum_k \alpha_{ijk} |Y_{jk}| = \sigma_i(X) + \sigma_i(Y)$$

so that
\[ F(X + Y) = \max_i \left\{ \sigma_i(X + Y) \right\} \leq \max_i \left\{ \sigma_i(X) + \sigma_i(Y) \right\} \]

\[ \leq \max_i \left\{ \sigma_i(X) \right\} + \max_i \left\{ \sigma_i(Y) \right\} = F(X) + F(Y) \]

Problem A with this class of norms becomes

Problem B: maximize \( Z(M) = \sum_i \sum_j \beta_{ij} M_{ij} \) \hspace{1cm} (3.5)

subject to \( \max_i \left( \sum_{j=1}^{4} \sum_{k=1}^{4} |\alpha_{ijk} M_{jk}| \right) \leq E \) and \( M_{jk} = M_{kj} \).

This problem obviously is equivalent to

Problem C: maximize \( Z(M) = \sum_i \sum_j \beta_{ij} M_{ij} \) \hspace{1cm} (3.6)

subject to \( \sum_{j=1}^{4} \sum_{k=1}^{4} |\alpha_{ijk} M_{jk}| \leq E \) and \( M_{jk} = M_{kj} \).

Problem C may be transformed into a standard linear programming problem by making the substitutions \( M_{ij} = P_{ij} - N_{ij} \) and \( |M_{ij}| = P_{ij} + N_{ij} \), where \( P_{ij} \) and \( N_{ij} \) are non-negative real numbers. To prove that this substitution gives the correct result, first eliminate the symmetry constraint, giving
Problem \( C' \): maximize \[ W(M) = \sum_{j=1}^{4} \sum_{k=j}^{4} \theta_{jk} M_{jk} \]

subject to \[ \sum_{j=1}^{4} \sum_{k=j}^{4} \alpha'_{ijk} |M_{jk}| \leq E \]

where \[
\alpha'_{ijk} = \begin{cases} 
\alpha_{ijk} & j=k \\
\alpha_{ijk} + \alpha_{ikj} & j \neq k 
\end{cases}
\]

and \[
\theta'_{ij} = \begin{cases} 
\beta_{ij} & i=j \\
\beta_{ij} + \beta_{ji} & i \neq j 
\end{cases}
\]

Then we have the following theorem:

**Theorem:** Let problem \( D \) be defined as:

\[
\text{maximize } Z(P,N) = \sum_{j=1}^{4} \sum_{k=j}^{4} \theta_{jk} (P_{jk} - N_{jk})
\]

subject to \[ \sum_{j=1}^{4} \sum_{k=j}^{4} \alpha'_{ijk} (P_{jk} + N_{jk}) \leq E \text{ and } P_{ij} \geq 0, N_{ij} \geq 0 \]

Then the optimal \( W \) from problem \( C' \) is equal to the optimal \( Z \) from problem \( D \).

**Proof:** Let \( M^* \) be a solution of problem \( C' \), and let \( W^* = W(M^*) \). If we make the substitutions
\[ P_{jk} = \begin{cases} M_{jk}^* & M_{jk}^* \geq 0 \\ 0 & M_{jk}^* < 0 \end{cases} \]

and

\[ N_{jk} = \begin{cases} 0 & M_{jk}^* \geq 0 \\ -M_{jk}^* & M_{jk}^* < 0 \end{cases} \]

then we have \( M_{ij}^* = P_{ij} - N_{ij} \), and \( |M_{ij}^*| = P_{ij} + N_{ij} \). Making these substitutions in problem \( C' \) gives

\[ W^* = W(M^*) = \sum_{j=1}^{4} \sum_{k=j}^{4} \beta^*_{jk} (P_{jk} - N_{jk}) = Z(P, N) \]

\[ \sum_{j=1}^{4} \sum_{k=j}^{4} \alpha^*_{ijk} (P_{jk} + N_{jk}) \leq E \text{ and } P_{ij} \geq 0, N_{ij} \geq 0. \]

The conditions for problem \( D \) are satisfied, so we must have \( W^* \leq Z^* \), where \( Z^* \) is the optimal value of \( Z \) obtained from problem \( D \).

Likewise, let \( P^* \) and \( N^* \) be an optimal solution to problem \( D \). Then for every pair of indices \((j,k)\) we have \( \beta^*_{jk} > 0 \), \( \beta^*_{jk} = 0 \), or \( \beta^*_{jk} < 0 \). If \( \beta^*_{jk} > 0 \), then we must have \( N_{jk}^* = 0 \). Otherwise, we could substitute \( P_{jk}^* + N_{jk}^* \) for \( P_{jk} \) and 0 for \( N_{jk} \); these new values still satisfy the required constraints, but increase the objective function, contradicting the fact that \((P^*, N^*)\) is optimal. Similarly, if \( \beta^*_{jk} < 0 \), then we must have \( P_{jk}^* = 0 \). If \( \beta^*_{jk} = 0 \), then we may take \( P_{jk}^* = N_{jk}^* = 0 \), since this leaves the constraints satisfied and has no effect on the objective function. Therefore we always have either \( P_{jk}^* = 0 \) or \( N_{jk}^* = 0 \). Taking \( M_{ij} = P_{ij}^* - N_{ij}^* \), it follows that
\[ |M_{ij}| = P_{ij} + N_{ij} \]. Making these substitutions in problem D,

\[ Z^* = Z(P^*, N^*) = \sum_{j=1}^{4} \sum_{i=k=j}^{4} J_{jk} M_{jk} \leq W^* \]

\[ \sum_{j=1}^{4} \sum_{i=k=j}^{4} \alpha'_{ijk} |M_{jk}| \leq E \]

Therefore \( W^* \leq Z^* \leq W^* \), proving the theorem.

Now that torque error bounds can be obtained from pseudo-inertia errors, these results must be incorporated into the trajectory planning process. Direct use of the results derived above in the trajectory planner described in [5] is not easy, since this trajectory planner requires that we solve (1.5) for \( \dot{\mu} \) in terms of \( \lambda \), \( \mu \), and \( u_i \). This solution is required because the trajectory planner must convert torque ranges into \( \dot{\mu} \) ranges. When errors are introduced, we have

\[ u_i^{\min}(\lambda, \mu) \leq M_i \dot{\mu} + Q_i \mu^2 + R_i \mu + S_i + \min_{\|\Delta f_r\| \leq E} \left\{ \delta M_i \dot{\mu} + \delta Q_i \mu^2 + \delta S_i \right\} \]

\[ \leq M_i \dot{\mu} + Q_i \mu^2 + R_i \mu + S_i + \max_{\|\Delta f_r\| \leq E} \left\{ \delta M_i \dot{\mu} + \delta Q_i \mu^2 + \delta S_i \right\} \]

\[ \leq u_i^{\max}(\lambda, \mu). \]

For given \( \lambda \) and \( \mu \), these inequalities determine a range of values of \( \dot{\mu} \). However, the worst-case values of \( \delta M_i, \delta Q_i, \) and \( \delta S_i \) depend upon \( \dot{\mu} \), which in turn depends upon the values of \( \delta M_i, \delta Q_i, \) and \( \delta S_i \), so finding the allowable range of values of \( \dot{\mu} \) explicitly is
difficult. Of course these equations can be solved numerically. For example, to find the
maximum allowable value of \( \dot{\mu} \), the equation

\[
M_i \ddot{\mu} + Q_i \mu^2 + R_i \mu + S_i + \max_{\|\Delta I_N\| \leq E} \left\{ \delta M_i \dot{\mu} + \delta Q_i \mu^2 + \delta S_i \right\} = u_i^{\text{max}}(\lambda, \mu)
\]

can be solved by bisection for \( \dot{\mu} \).

A simpler solution to the problem is to use one of the trajectory planners described in [6] or [7]. These trajectory planners only need to have available a test function which determines whether or not a given \((\lambda, \mu, \dot{\mu})\) triple requires excessive torque; in effect, they automatically perform the numerical search for the allowable values of \( \dot{\mu} \). But such a function is easily constructed, since for a given \((\lambda, \mu, \dot{\mu})\) we can easily minimize or maximize \( \delta u_i \) in (2.16), and see if \( u_i + \delta u_i^{\text{max}} \) exceeds \( u_i^{\text{max}}(\lambda, \mu) \) or \( u_i + \delta u_i^{\text{min}} \) falls below \( u_i^{\text{min}}(\lambda, \mu) \). In particular, the following algorithm checks to see if a particular \((\lambda, \mu, \dot{\mu})\) triple meets all the torque constraints:

```plaintext
for each joint \( i \) do
  begin
    compute \( u_i^N = M_i(\lambda) \dot{\mu} + Q_i(\lambda) \mu^2 + R_i(\lambda) \mu + S_i(\lambda) \)
    compute \( \delta u_i^{\text{max}} = \max_{\|\Delta I_N\| \leq E} \left\{ \delta M_i(\lambda, \Delta I_N) \dot{\mu} + \delta Q_i(\lambda, \Delta I_N) \mu^2 + \delta S_i(\lambda, \Delta I_N) \right\} \)
    compute \( \delta u_i^{\text{min}} = \min_{\|\Delta I_N\| \leq E} \left\{ \delta M_i(\lambda, \Delta I_N) \dot{\mu} + \delta Q_i(\lambda, \Delta I_N) \mu^2 + \delta S_i(\lambda, \Delta I_N) \right\} \)
    if \( u_i^N + \delta u_i^{\text{min}} < u_i^{\text{min}}(\lambda, \mu) \), then return REJECT
    if \( u_i^N + \delta u_i^{\text{max}} > u_i^{\text{max}}(\lambda, \mu) \), then return REJECT
  end
return ACCEPT.
```

.Payload Uncertainties

18
It should be noted that this function is called for each \((\lambda, \mu)\) pair; it does not, for example, reject a \((\lambda, \mu, \dot{\mu})\) triple based on an error which is computed for all positions or all velocities. As a consequence, speed is sacrificed only when absolutely necessary to guarantee that the trajectory will be realizable for all payloads within the allowable range.

4. NUMERICAL EXAMPLE

As an example, we will apply the methods of the previous section to the first three joints of the Bendix PACS robot arm. This arm is cylindrical in configuration and is driven by DC servos. Its dynamics and actuator characteristics are described in Table 1. The trajectory planner used is described in [6].

The kinematics of the PACS arm are quite simple. If the coordinate frames of the base and hand are as shown in Figure 1, then the coordinate transform \(T_3\) is easily shown to be

\[
T_3 = \begin{bmatrix}
\cos \theta & 0 & -\sin \theta & -r \sin \theta \\
\sin \theta & 0 & \cos \theta & r \cos \theta \\
0 & -1 & 0 & z \\
0 & 0 & 0 & 1
\end{bmatrix}.
\] (4.1)

The partial derivatives of \(T_3\) are

\[
\frac{\partial T_3}{\partial z} = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}, \quad \frac{\partial T_3}{\partial \theta} = \begin{bmatrix}
-\sin \theta & 0 & -\cos \theta & -r \cos \theta \\
\cos \theta & 0 & -\sin \theta & -r \sin \theta \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}.
\] (4.2)
\[
\frac{\partial T_3}{\partial r} = \begin{bmatrix}
0 & 0 & 0 & -\sin \theta \\
0 & 0 & 0 & \cos \theta \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}.
\]

(4.3)

There are two non-zero second partials; they are

\[
\frac{\partial^2 T_3}{\partial \theta^2} = \begin{bmatrix}
-\cos \theta & 0 & \sin \theta & r \sin \theta \\
-\sin \theta & 0 & -\cos \theta & -\cos \theta \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

and

\[
\frac{\partial^2 T_3}{\partial r \partial \theta} = \begin{bmatrix}
0 & 0 & 0 & -\cos \theta \\
0 & 0 & 0 & -\sin \theta \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}.
\]

(4.4)

We are now in a position to compute the \( \delta M_i \). If we let \( H = \Delta I_N \) and define

\[
m_{ij} = Tr \left( \frac{\partial T_N}{\partial q^i} H \frac{\partial T_N}{\partial q^j} \right)
\]

then we have

\[
\delta M_i = m_{ij} \frac{dq^j}{d\lambda}.
\]

Computing the \( m_{ij} \),

\[
m_{zz} = Tr \left( \frac{\partial T_3}{\partial z} H \frac{\partial T_3}{\partial z} \right) \quad \text{and} \quad \frac{\partial T_3}{\partial z} H \frac{\partial T_3}{\partial z} = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & H_{44} & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}.
\]

Taking the trace of this gives \( m_{zz} = H_{44} \).

\[
m_{z\theta} = m_{\theta z} = Tr \left( \frac{\partial T_3}{\partial \theta} H \frac{\partial T_3}{\partial \theta} \right)
\]
\[ \frac{\partial \mathbf{T}_3}{\partial z} \mathbf{H} \frac{\partial \mathbf{T}_3^T}{\partial \theta} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ H_{14} & H_{24} & H_{34} & H_{44} \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} -\sin \theta & \cos \theta & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -\cos \theta & -\sin \theta & 0 & 0 \\ -r \cos \theta & -r \sin \theta & 0 & 0 \end{bmatrix}. \]

The trace of this matrix is easily found to be zero.

\[ m_{rr} = m_{zz} = Tr \left( \frac{\partial \mathbf{T}_3}{\partial z} \mathbf{H} \frac{\partial \mathbf{T}_3^T}{\partial z} \right) \]

\[ \frac{\partial \mathbf{T}_3}{\partial z} \mathbf{H} \frac{\partial \mathbf{T}_3^T}{\partial \theta} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ H_{14} & H_{24} & H_{34} & H_{44} \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -\cos \theta & -\sin \theta & 0 & 0 \end{bmatrix}. \]

The trace of this matrix also is zero.

\[ m_{\theta \theta} = Tr \left( \frac{\partial \mathbf{T}_3}{\partial \theta} \mathbf{H} \frac{\partial \mathbf{T}_3^T}{\partial \theta} \right) \]

\[ \frac{\partial \mathbf{T}_3}{\partial \theta} \mathbf{H} \frac{\partial \mathbf{T}_3^T}{\partial \theta} = \begin{bmatrix} -\sin \theta & 0 & -\cos \theta & -r \cos \theta \\ \cos \theta & 0 & -\sin \theta & -r \sin \theta \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} & H_{13} & H_{14} \\ H_{12} & H_{22} & H_{23} & H_{24} \\ H_{13} & H_{23} & H_{33} & H_{34} \\ H_{14} & H_{24} & H_{34} & H_{44} \end{bmatrix} \begin{bmatrix} -\sin \theta & \cos \theta & 0 & 0 \\ -\cos \theta & -\sin \theta & 0 & 0 \\ -r \cos \theta & -r \sin \theta & 0 & 0 \end{bmatrix}. \]

The diagonal entries of this matrix are

\[ \epsilon_{11} = H_{11} \sin^2 \theta + 2H_{13} \sin \theta \cos \theta + 2H_{14} r \sin \theta \cos \theta + H_{33} \cos^2 \theta + 2H_{34} r \cos^2 \theta + H_{44} r^2 \cos^2 \theta \]

\[ \epsilon_{22} = H_{11} \cos^2 \theta - 2H_{13} \sin \theta \cos \theta - 2H_{14} r \sin \theta \cos \theta + H_{33} \sin^2 \theta + 2H_{34} r \sin^2 \theta + H_{44} r^2 \sin^2 \theta \]

\[ \epsilon_{33} = \epsilon_{44} = 0. \]
Adding these up to get the trace,

\[ m_{\theta \theta} = \text{Tr} \left( \frac{\partial T_3}{\partial \theta} H \frac{\partial T_3^T}{\partial \theta} \right) = H_{11} + H_{33} + 2rH_{34} + r^2H_{44} \]

\[ m_{\theta r} = m_{r \theta} = \text{Tr} \left( \frac{\partial T_3}{\partial \theta} H \frac{\partial T_3^T}{\partial r} \right). \]

The diagonal entries of \( \frac{\partial T_3}{\partial \theta} H \frac{\partial T_3^T}{\partial r} \) are

\[ e_{11} = H_{14}\sin^2\theta + H_{34}\sin\theta\cos\theta + H_{44}r\sin\theta\cos\theta \]

\[ e_{22} = H_{14}\cos^2\theta - H_{34}\sin\theta\cos\theta - H_{44}r\sin\theta\cos\theta \]

\[ e_{33} = e_{44} = 0. \]

Adding these up gives \( m_{\theta r} = H_{14}. \)

\[ m_{rr} = \text{Tr} \left( \frac{\partial T_3}{\partial r} H \frac{\partial T_3^T}{\partial r} \right) \]

\[ \frac{\partial T_3}{\partial r} H \frac{\partial T_3^T}{\partial r} = \begin{bmatrix} 0 & 0 & 0 & -\sin\theta \\ 0 & 0 & 0 & \cos\theta \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} & H_{13} & H_{14} \\ H_{12} & H_{22} & H_{23} & H_{24} \\ H_{13} & H_{23} & H_{33} & H_{34} \\ H_{14} & H_{24} & H_{34} & H_{44} \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -\sin\theta & \cos\theta & 0 & 0 \end{bmatrix} \]

\[ = \begin{bmatrix} H_{44}\sin^2\theta & -H_{44}\sin\theta\cos\theta & 0 & 0 \\ -H_{44}\sin\theta\cos\theta & H_{44}\cos^2\theta & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}. \]

The trace of this is \( m_{rr} = H_{44}. \)
We can now find the $\delta M_i$. We have

$$\delta M_z = H_{44} \frac{dz}{d\lambda}$$

$$\delta M_\theta = (H_{11} + H_{33} + 2rH_{34} + r^2H_{44}) \frac{d\theta}{d\lambda} + H_{14} \frac{dr}{d\lambda}$$

$$\delta M_r = H_{14} \frac{d\theta}{d\lambda} + H_{44} \frac{dr}{d\lambda}$$

If we define $c_{ijk}$ by $c_{ijk} = Tr \left\{ \frac{\partial^2 T_N}{\partial q_i \partial q_j} H \frac{\partial T_N^T}{\partial q_k} \right\}$, then we have

$$\delta Q_i = m_{ij} \frac{d^2 f^j}{d\lambda^2} + c_{ijk} \frac{df^j}{d\lambda} \frac{df^k}{d\lambda}.$$ 

We now compute the $c_{ijk}$. Only six cases need to be considered, since all but two of the second partials of $T_3$ are zero.

$$c_{\theta \theta} = Tr \left\{ \frac{\partial^2 T_3}{\partial \theta^2} H \frac{\partial T_3}{\partial z} \right\}$$

$$\frac{\partial^2 T_3}{\partial \theta^2} H \frac{\partial T_3}{\partial z} = \begin{bmatrix}
-\cos \theta & 0 & \sin \theta & r \sin \theta \\
-\sin \theta & 0 & -\cos \theta & -r \cos \theta \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix} \begin{bmatrix}
H_{11} & H_{12} & H_{13} & H_{14} \\
H_{12} & H_{22} & H_{23} & H_{24} \\
H_{13} & H_{23} & H_{33} & H_{34} \\
H_{14} & H_{24} & H_{34} & H_{44}
\end{bmatrix} \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}.$$ 

The trace of this matrix is zero.

$$c_{\theta \theta} = Tr \left\{ \frac{\partial^2 T_3}{\partial \theta^2} H \frac{\partial T_3}{\partial \theta} \right\}.$$ 

The diagonal terms of $\frac{\partial^2 T_3}{\partial \theta^2} H \frac{\partial T_3}{\partial \theta}$ are
\[ e_{11} = H_{11}\sin\theta\cos\theta - H_{13}\sin^2\theta - H_{14}r\sin^2\theta + H_{15}\cos^2\theta - H_{33}\sin\theta\cos\theta \]
\[ - H_{34}r\sin\theta\cos\theta + H_{14}r\cos^2\theta - H_{34}r\sin\theta\cos\theta - H_{44}r^2\sin\theta\cos\theta \]
\[ e_{22} = -H_{11}\sin\theta\cos\theta - H_{13}\cos^2\theta - H_{14}r\cos^2\theta + H_{15}\sin^2\theta + H_{33}\sin\theta\cos\theta \]
\[ + H_{34}r\sin\theta\cos\theta + H_{14}r\sin^2\theta + H_{34}r\sin\theta\cos\theta + H_{44}r^2\sin\theta\cos\theta \]
\[ e_{33} = e_{44} = 0 \]

The trace is zero.

\[ c_{\theta\theta} = Tr \left( \frac{\partial^2 T_3}{\partial \theta^2} H \frac{\partial T_3}{\partial r} \right). \]

The diagonal terms of \( \frac{\partial^2 T_3}{\partial \theta^2} H \frac{\partial T_3}{\partial r} \) are

\[ e_{11} = H_{14}\sin\theta\cos\theta - H_{34}\sin^2\theta - H_{44}r\sin^2\theta \]
\[ e_{22} = -H_{14}\sin\theta\cos\theta - H_{34}\cos^2\theta - H_{44}r\cos^2\theta \]
\[ e_{33} = e_{44} = 0. \]

The trace therefore is \( c_{\theta\theta} = -H_{34} - H_{44}r \).

\[ c_{zz} = Tr \left( \frac{\partial^2 T_3}{\partial \theta \partial r} H \frac{\partial T_3}{\partial z} \right) \]

\[ \frac{\partial^2 T_3}{\partial \theta \partial r} H \frac{\partial T_3}{\partial z} = \begin{bmatrix} 0 & 0 & 0 & -\cos\theta \\ 0 & 0 & 0 & -\sin\theta \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} & H_{13} & H_{14} \\ H_{12} & H_{22} & H_{23} & H_{24} \\ H_{13} & H_{23} & H_{33} & H_{34} \\ H_{14} & H_{24} & H_{34} & H_{44} \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}. \]
The trace of this matrix is zero.

\[ c_{\theta r} = Tr \left( \frac{\partial^2 T_3}{\partial \theta \, \partial r} H \frac{\partial T_3}{\partial \theta} \right). \]

The diagonal terms of \( \frac{\partial^2 T_3}{\partial \theta \, \partial r} H \frac{\partial T_3}{\partial \theta} \) are

\[ e_{11} = H_{44} \sin \theta \cos \theta + H_{34} \cos^2 \theta + H_{44} r \cos^2 \theta \]

\[ e_{22} = -H_{44} \sin \theta \cos \theta + H_{34} \sin^2 \theta + H_{44} r \sin^2 \theta \]

\[ e_{33} = e_{44} = 0. \]

The trace is \( c_{\theta r} = H_{34} + H_{44} r \).

\[ c_{r \theta r} = Tr \left( \frac{\partial^2 T_3}{\partial \theta \, \partial r} H \frac{\partial T_3}{\partial r} \right). \]

The diagonal terms of \( \frac{\partial^2 T_3}{\partial \theta \, \partial r} H \frac{\partial T_3}{\partial r} \) are

\[ e_{11} = H_{44} \sin \theta \cos \theta \]

\[ e_{22} = -H_{44} \sin \theta \cos \theta \]

\[ e_{33} = e_{44} = 0. \]

The trace is zero.

Calculating the \( \delta Q_1 \),

\[ \delta Q_z = H_{44} \frac{d^2 z}{d \lambda^2} \]
\[ \delta Q_\theta = (H_{11} + H_{33} + 2rH_{34} + r^2H_{44}) \frac{d^2 \theta}{d \lambda^2} + H_{14} \frac{d^2 r}{d \lambda^2} + 2(H_{34} + rH_{44}) \frac{dr}{d \lambda} \frac{d \theta}{d \lambda} \]

\[ \delta Q_r = H_{14} \frac{d^2 \theta}{d \lambda^2} + H_{44} \frac{d^2 r}{d \lambda^2} - (H_{34} + rH_{44}) \left( \frac{d \theta}{d \lambda} \right)^2.\]

The \( \delta S_i \), the gravitational error coefficients, are easily found to be \( \delta S_z = H_{44} g \)
and \( \delta S_\theta = \delta S_r = 0 \), where \( g \) is the acceleration due to gravity.

We will use the norm

\[ ||H|| = \sum_{i=1}^{4} \sum_{j=1}^{4} \alpha_{ij} |H_{ij}| \]

where \( \alpha_{ij} > 0 \). This makes the problem of finding the error bounds very simple. It is easily seen that if the functional to be maximized is

\[ Z = \sum_i \sum_j \beta_{ij} H_{ij} \]

then the maximum over \( H \) for \( ||H|| \leq E \) occurs when all the \( H_{ij} \) are zero except for those \( H_{ij} \) for which \( \left| \frac{\beta_{ij}}{\alpha_{ij}} \right| \) is a maximum; this number times \( E \) is also the maximum value of \( Z \). If we use

\[ \alpha_{ij} = \begin{cases} 1 & i = j \\ 1/2 & i \neq j \end{cases} \]

then the resulting bounds on the \( |\delta u_i| \) are

\[ |\delta u_z| \leq \left| \frac{dz}{d \lambda} \dot{\mu} + \frac{d^2 z}{d \lambda^2} \mu^2 + g \right| ||\Delta I_N|| \]
\[ |\delta u_\theta| \leq \max \left\{ \left| \frac{d\theta}{d\lambda} \mu + \frac{d^2\theta}{d\lambda^2} \mu^2 \right|, \left| \frac{dr}{d\lambda} \mu + \frac{d^2r}{d\lambda^2} \mu^2 \right|, \right. \\
\left. 2r \frac{d\theta}{d\lambda} \mu + 2r \frac{d^2\theta}{d\lambda^2} \mu^2 + 2 \frac{dr}{d\lambda} \frac{d\theta}{d\lambda} \mu^2 \right\} \|\Delta I_N\| \]

\[ |\delta u_r| \leq \max \left\{ \left| \frac{d\theta}{d\lambda} \mu + \frac{d^2\theta}{d\lambda^2} \mu^2 \right|, \left( \frac{d\theta}{d\lambda} \right)^2 \mu^2 \right\}, \]

\[ \left| \frac{dr}{d\lambda} \mu + \frac{d^2r}{d\lambda^2} \mu^2 - r \left( \frac{d\theta}{d\lambda} \right)^2 \mu^2 \right| \|\Delta I_N\|. \]

The joint torques that can be applied to the PACS arm are limited by saturation of the drive motors, which gives a constant torque or force limit for each joint. In addition, there are limits on the voltages which can be applied to the motors, so we need to know how the errors in the joint torques translate into errors in the motor voltages. It will be assumed that the back-EMF constant, winding resistance, and voltage source resistance are known exactly, though this is not necessary. Since for a given speed voltage is a linear function of torque, i.e., \( V_i = A_i u_i + B_i \), the change in voltage will be \( \delta V_i = A_i \delta u_i \). These changes in voltage can then be added to the nominal voltage and tested against the motor voltage limits in much the same way that the torques are checked against the motor torque saturation limits.

The perturbation to the nominal dynamics of the manipulator will be caused by placing a cube with edges of length \( L \) and uniform mass density \( \rho \) in the gripper of the robot, with its center of mass coincident with the origin of the end effector coordinate
system. The pseudo-inertia of this cube is

\[
\Delta I_3 = \begin{bmatrix}
\frac{1}{12} \rho L^5 & 0 & 0 & 0 \\
0 & \frac{1}{12} \rho L^5 & 0 & 0 \\
0 & 0 & \frac{1}{12} \rho L^5 & 0 \\
0 & 0 & 0 & \rho L^3
\end{bmatrix}
\]

The norm of this “error” is

\[
\|\Delta I_3\| = \rho L^3 + \frac{1}{4} \rho L^5
\]

The maximum torque error for a given range of pseudo-inertia errors occurs when the error bound \(E\) is precisely equal to the norm of the actual pseudo-inertia error. Therefore the most stringent test of the results of the previous section is to use a tight error bound, i.e.,

\[
E = \|\Delta I_3\|
\]

This has been done for a cube with sides of 5 centimeters and densities of 0, 6, 12, 18, 24, and 30 grams/cc. The path traversed is a straight line from the (Cartesian) point (0.7,0.7,0.1) to (0.4,-0.4,0.4). For comparison, the true optimal solution has been calculated, using the actual dynamics (including the effects of the cube in the gripper). The results are summarized in Tables 2 through 6. Table 2 gives traversal times for the true optimal solution and for the case in which errors are included. The “percent difference” column gives the percentage by which the true optimal traversal time is exceeded. Tables 3 and 4 give minimum and maximum voltages, respectively. The actual and nominal values are both computed for the “nominal” trajectory, i.e. the
trajectory which is calculated with errors included. The actual voltages are those required to move the robot with the cube in the gripper, while the nominal values are those which are required without the cube (i.e. with the nominal payload.) The minimum and maximum voltages available are -40 and 40 volts, and it is easily seen that these limits are not exceeded for any joint or for either payload. Tables 5 and 6 give the minimum and maximum torques or forces for each joint. The torque or force limits are given at the head of the column for the appropriate joint; again, the limits are not exceeded.

The phase plane (\( \lambda \) vs. \( \mu \)) plot and motor voltage vs. time plot for the zero-density case are shown in Figures 2a and 2b. Since the error is zero in this case, the results are exact. For a density of 12 grams/cc., the optimal and nominal (i.e. with errors included) phase plane plots are shown in Figure 3a. Figure 3b gives joint positions vs. time; \( \theta \) and \( r \) are in meters, \( \theta \) in radians. Figures 3c through 3e give nominal and actual motor voltages required to drive the robot along the nominal trajectory for the \( \theta \), \( r \), and \( r \) joints respectively. Figures 3f through 3h give the nominal and actual torques. (The nominal torques/voltages are those which would be required if the actual payload were identical to the nominal payload. The actual torques are the torques required to keep the robot with the perturbed payload on the nominal trajectory.) Figures 4a through 4h show the same plots for a density of 24 grams/cc.

It was noted above that none of the joint torque or voltage constraints was violated. However, the minimum voltage for the \( r \) joint at one point meets the lower voltage limit. This indicates that the trajectory which is generated when payload errors are included is indeed the fastest possible trajectory for the given range of possible payloads; for this particular point, the worst-case payload happens to have the same
characteristics as the actual payload. A larger payload would have resulted in violation of a voltage constraint.

Another point to consider is the relationship between the nominal and optimal phase trajectories. It is expected that the nominal phase trajectory will be lower than the optimal trajectory; a nominal trajectory which was higher than the optimal one would lead to a contradiction of the optimality of the optimal trajectory. Also, the difference between the optimal and nominal trajectories increases as the payload error bound increases. This would be expected, since the nominal trajectory must accommodate all payloads within a given range; as the range of payloads increases, the worst-case errors also increase, resulting in more restrictive limits on the nominal torques, and hence slower trajectory traversal times.

5. CONCLUSIONS

A method for including payload inertia errors in the manipulator trajectory planning process has been presented. Errors in the payload inertia are characterized by bounds on the norm of the difference between the actual and nominal pseudo-inertias of the payload. Given such a bound, it has been shown that a trajectory can be constructed which meets all torque and force constraints for all actual payloads, provided that the norm of the difference of the pseudo-inertias of the actual and nominal payloads differs by less than the given error bound. This technique was applied to the Bendix PACS robot for a number of different payloads, and the resulting trajectories were shown not to violate any joint torque or motor voltage constraints. In the worst case, in which the actual payload mass differs from the nominal mass by approximately one third of the robot’s rated maximum load, the traversal time was less than twenty percent over the optimal value.
