Retrospective-Cost Adaptive Control of Uncertain Hammerstein Systems Using a NARMAX Controller Structure

Jin Yan *, Anthony M. D’Amato † and Dennis S. Bernstein ‡

University of Michigan, 1320 Beal Ave., Ann Arbor, MI 48109

We apply an extension of retrospective cost adaptive control (RCAC) to a command-following problem for uncertain Hammerstein systems. In particular, RCAC with a NARMAX controller structure is applied to linear systems cascaded with input nonlinearities. We assume that one Markov parameter of the linear plant is known. RCAC also uses knowledge of the monotonicity properties of the input nonlinearity. The goal is to determine whether RCAC with a NARMAX controller structure can improve the command-following performance compared to the linear RCAC controller.

I. Introduction

Many practical systems can be modeled as linear systems cascaded with input and output nonlinearities. Systems with input nonlinearities are called Hammerstein systems. Examples of memoryless nonlinearities include saturation and deadzone, while nonlinearities with memory include hysteretic actuators and sensors. Identification and control techniques have been extensively developed for these systems.1-3,5

In practice, however, the linear component of the system as well as the nonlinearities may be uncertain. In this case, robust control techniques can be used.4 However, adaptive control methods may be desirable to allow the controller to tune itself to the actual plant characteristics, especially when unexpected changes can occur during plant operation.

In recent research6-8 we demonstrated the ability of retrospective cost adaptive control (RCAC)9-14 to control systems involving linear dynamics with input and output nonlinearities. In all of these papers the goal is to adapt an instantaneous linear controller for a nonlinear plant. Although RCAC is able to tune the linear controller to the command signal and nonlinear characteristics of the plant, the ability of the linear controller to produce accurate command following is limited by the distortion introduced by the nonlinearities. The objective of the present paper is to develop a technique for reducing this distortion.

The approach that we take in the present paper is to replace the linear controller structure of RCAC by a nonlinear controller structure. A simple and effective way to do this is to use a NARMAX (nonlinear ARMAX) controller structure that is linear in parameters. NARMAX models have been used extensively for system identification15-17 and as a plant model for adaptive control.18 The approach of the present paper differs from prior work by using a NARMAX model structure for the adaptive controller itself, where the nonlinearities are chosen prior to controller implementation and the controller coefficients are updated online by RCAC.

*Graduate Student, Aerospace Engineering Department
†NASA GSRP Fellow, Aerospace Engineering Department
‡Professor, Aerospace Engineering Department
The controller nonlinearities can be applied to either the input to the controller (NARMAX/I), the output of the controller (NARMAX/O), or both (NARMAX/IO). The choice of NARMAX controller structure is chosen to reflect the presence of the unknown input or output nonlinearities in the plant with the goal of at least partially inverting these nonlinearities to reduce the distortion that degrades the command-following accuracy. In the present paper we investigate various choices of the controller nonlinearities in order to determine their effectiveness in improving the closed-loop performance. The goal is to determine controller nonlinearities that are effective for large classes of uncertain input nonlinearities.

The contents of the paper are as follows. In Section II, we describe the Hammerstein command-following problem. In Section III, we apply the NARMAX controller structure to Hammerstein systems. In particular, we apply an extension of RCAC using auxiliary nonlinearities, and employ a nonlinear controller structure to reduce the command-following distortion introduced by the input nonlinearities. Numerical results are also presented in Section IV, and conclusions are given in Section V.

II. Hammerstein Command-following Problem

Consider the SISO discrete-time Hammerstein system

\[
\begin{align*}
    x(k+1) &= A x(k) + B N(u(k)), \\
    y(k) &= E_1 x(k),
\end{align*}
\]

where \(x(k) \in \mathbb{R}^n, u(k), y(k) \in \mathbb{R}, w(k) \in \mathbb{R}^d, N : \mathbb{R} \to \mathbb{R},\) and \(k \geq 0.\) We consider the Hammerstein command-following problem with performance variable

\[
z(k) = y(k) - r(k),
\]

where \(z(k), r(k) \in \mathbb{R}.\) The goal is to develop an adaptive output feedback controller that minimizes the command-following error \(z\) with minimal modeling information about the dynamics, and input nonlinearity \(N.\) We assume that measurements of \(z(k)\) are available for feedback; however, measurements of \(v(k) = N(u(k))\) are not available. A block diagram for (1)-(3) is shown in Figure 1.

![Block Diagram](image)

Figure 1. Adaptive command-following problem for a Hammerstein plant. We assume that measurements of \(z(k)\) are available for feedback; however, measurements of \(v(k) = N(u(k))\) are not available. The feedforward path is optional.

III. Retrospective-Cost Adaptive Control

III.A. Retrospective Cost with Adaptive Regularization

For \(i \geq 1,\) define the Markov parameter

\[
H_i \triangleq E_1 A^{i-1} B.
\]

For example, \(H_1 = E_1 B\) and \(H_2 = E_1 AB.\) Let \(\ell\) be a positive integer. Then, for all \(k \geq \ell,\)

\[
x(k) = A^\ell x(k - \ell) + \sum_{i=1}^{\ell} A^{\ell-1} B N(u(k - i)),
\]

where \(A, B, E_1, G, N, z, r, v, u, y, z(k), r(k) \in \mathbb{R},\) and \(k \geq 0.\)
and thus
\[ z(k) = E_1 A^\ell x(k - \ell) + \overline{H} \overline{V}(k - 1) - r(k), \]  

where
\[ \overline{H} \triangleq \begin{bmatrix} H_1 & \cdots & H_\ell \end{bmatrix} \in \mathbb{R}^{1 \times \ell} \]

and
\[ \overline{V}(k - 1) \triangleq \begin{bmatrix} \mathcal{N}(u(k - 1)) \\ \vdots \\ \mathcal{N}(u(k - \ell)) \end{bmatrix}. \]

Next, we rearrange the columns of \( \overline{H} \) and the components of \( \overline{V}(k - 1) \) and partition the resulting matrix and vector so that
\[ \overline{H} \overline{V}(k - 1) = \mathcal{H} \mathcal{V}''(k - 1) + \mathcal{H} \mathcal{V}(k - 1), \]

where \( \mathcal{H} \in \mathbb{R}^{1 \times (\ell - l_v)}, \mathcal{H} \in \mathbb{R}^{1 \times l_v}, \mathcal{V}''(k - 1) \in \mathbb{R}^{\ell - l_v}, \) and \( \mathcal{V}(k - 1) \in \mathbb{R}^{l_v} \). Then, we can rewrite (5) as
\[ z(k) = \mathcal{S}(k) + \mathcal{H} \mathcal{V}(k - 1), \]

(7)

Next, for \( j = 1, \ldots, s \), we rewrite (7) with a delay of \( k_j \) time steps, where \( 0 \leq k_1 \leq k_2 \leq \cdots \leq k_s \), in the form
\[ z(k - k_j) = \mathcal{S}_j(k - k_j) + \mathcal{H}_j \mathcal{V}_j(k - k_j - 1), \]

(9)

where (8) becomes
\[ \mathcal{S}_j(k - k_j) \triangleq E_1 A^\ell x(k - k_j - \ell) + \mathcal{H}_j' \mathcal{V}_j'(k - k_j - 1) - r(k - k_j) \]

and (6) becomes
\[ H \mathcal{U}(k - k_j - 1) = \mathcal{H}_j' \mathcal{V}_j'(k - k_j - 1) + \mathcal{H}_j \mathcal{V}_j(k - k_j - 1), \]

where \( \mathcal{H}_j' \in \mathbb{R}^{1 \times (\ell - l_v)}, \mathcal{H}_j \in \mathbb{R}^{1 \times l_v}, \mathcal{V}_j'(k - k_j - 1) \in \mathbb{R}^{\ell - l_v}, \) and \( \mathcal{V}_j(k - k_j - 1) \in \mathbb{R}^{l_v} \). Now, by stacking \( z(k - k_1), \ldots, z(k - k_s) \), we define the extended performance
\[ Z(k) \triangleq \begin{bmatrix} z(k - k_1) \\ \vdots \\ z(k - k_s) \end{bmatrix} \in \mathbb{R}^s. \]

(10)

Therefore,
\[ Z(k) \triangleq \mathcal{S}(k) + \mathcal{H} \overline{V}(k - 1), \]

(11)

where
\[ \mathcal{S}(k) \triangleq \begin{bmatrix} \mathcal{S}_1(k - k_1) \\ \vdots \\ \mathcal{S}_s(k - k_s) \end{bmatrix} \in \mathbb{R}^s, \]
$\hat{V}(k-1)$ has the form

$$\hat{V}(k-1) \triangleq \begin{bmatrix} N((u(k-q_1)) \\ \vdots \\ N((u(k-q_{1,\psi})) \end{bmatrix} \in \mathbb{R}^{l_{\psi}},$$

where, for $i = 1, \ldots, l_{\psi}$, $k_1 \leq q_i \leq k_s + \ell$, and $\hat{\mathcal{G}} \in \mathbb{R}^{s \times l_{\psi}}$ is constructed according to the structure of $\hat{V}(k-1)$. The vector $\hat{V}(k-1)$ is formed by stacking $V_1(k-k_1-1), \ldots, V_s(k-k_s-1)$ and removing copies of repeated components.

Next, for $j = 1, \ldots, s$, we define the retrospective performance

$$\hat{z}_j(k-k_j) \triangleq \hat{s}_j(k-k_j) + \hat{\mathcal{G}}_j \hat{V}_j(k-k_j-1),$$

(12)

where the past controls $V_j(k-k_j-1)$ in (9) are replaced by the retrospective controls $\hat{V}_j(k-k_j-1)$. In analogy with (10), the extended retrospective performance for (12) is defined as

$$\hat{Z}(k) \triangleq \begin{bmatrix} \hat{z}_1(k-k_1) \\ \vdots \\ \hat{z}_s(k-k_s) \end{bmatrix} \in \mathbb{R}^s$$

and thus is given by

$$\hat{Z}(k) = \hat{s}(k) + \hat{\mathcal{G}} \hat{V}(k-1),$$

(13)

where the components of $\hat{V}(k-1) \in \mathbb{R}^{l_{\psi}}$ are the components of $\hat{V}_1(k-k_1-1), \ldots, \hat{V}_s(k-k_s-1)$ ordered in the same way as the components of $\hat{V}(k-1)$. Subtracting (11) from (13) yields

$$\hat{Z}(k) = Z(k) - \hat{\mathcal{G}} \hat{V}(k-1) + \hat{\mathcal{G}} \hat{V}(k-1).$$

(14)

Finally, we define the retrospective cost function

$$J(\hat{V}(k-1), k) \triangleq \hat{Z}^T(k)R(k)\hat{Z}(k),$$

(15)

where $R(k) \in \mathbb{R}^{s \times s}$ is a positive-definite performance weighting. The goal is to determine refined controls $\hat{V}(k-1)$ that would have provided better performance than the controls $U(k)$ that were applied to the system. The refined control values $\hat{V}(k-1)$ are subsequently used to update the controller.

Next, to ensure that (15) has a global minimizer, we consider the regularized cost

$$\hat{J}(\hat{V}(k-1), k) \triangleq \hat{Z}^T(k)R(k)\hat{Z}(k)$$

$$+ \eta(k)\hat{V}^T(k-1)\hat{V}(k-1),$$

(16)

where $\eta(k) \geq 0$. Substituting (14) into (16) yields

$$\hat{J}(\hat{V}(k-1), k) = \hat{V}(k-1)^T\mathcal{A}(k)\hat{V}(k-1)$$

$$+ \mathcal{B}(k)\hat{V}(k-1) + \mathcal{C}(k),$$

where

$$\mathcal{A}(k) \triangleq \hat{\mathcal{G}}^T R(k)\hat{\mathcal{G}} + \eta(k)I_{l_{\psi}},$$

$$\mathcal{B}(k) \triangleq 2\hat{\mathcal{G}}^T R(k)[Z(k) - \hat{\mathcal{G}} \hat{V}(k-1)],$$

$$\mathcal{C}(k) \triangleq Z^T(k)R(k)Z(k) - 2Z^T(k)R(k)\hat{\mathcal{G}} \hat{V}(k-1)$$

$$+ \hat{V}^T(k-1)\hat{\mathcal{G}}^T R(k)\hat{\mathcal{G}} \hat{V}(k-1).$$
If either $\hat{\mathbf{U}}$ has full column rank or $\eta(k) > 0$, then $A(k)$ is positive definite. In this case, $\hat{J}(\hat{V}(k - 1), k)$ has the unique global minimizer
\[
\hat{V}(k - 1) = -\frac{1}{2}A^{-1}(k)\mathbf{B}(k).
\] (17)

III.B. NARMAX Controller Construction

In this section, we assume a NARMAX structure for the adaptive controller, which uses a nonlinear difference equation to model the relation between the input $z$ and output $u$ of the controller. The nonlinear controller may include nonlinearities on the input to the controller (NARMAX/I), the output of the controller (NARMAX/O), or both (NARMAX/IO). The NARMAX controller structure is linear in the controller parameters, and linear regression is used to update the controller coefficients.

The control $u(k)$ is given by the strictly proper time-series controller of order $n_c$ written as
\[
u(k) = \sum_{j=1}^{p} \sum_{i=1}^{n_c} M_{ji}(k)f_j(u(k - i)) + \sum_{j=1}^{q} \sum_{i=1}^{n_c} N_{ji}(k)g_j(z(k - i)),
\] (18)
where, for all $j = 1, \ldots, p$, $i = 1, \ldots, n_c$, $M_{ji}(k) \in \mathbb{R}$, and $N_{ji}(k) \in \mathbb{R}$. The control (18) can be expressed as
\[
u(k) = \theta(k)\phi(k - 1),
\]
where
\[
\theta(k) \triangleq [M_{11}(k) \cdots M_{1n_c}(k) M_{21}(k) \cdots M_{2n_c}(k) \cdots M_{p1}(k) \cdots M_{pn_c}(k) \]
\[
N_{11}(k) \cdots N_{1n_c}(k) N_{21}(k) \cdots N_{2n_c}(k) \cdots N_{q1}(k) \cdots N_{qn_c}(k) \in \mathbb{R}^{p+q \times n_c}
\]
and
\[
\phi(k - 1) \triangleq [f_1(u(k-1)) \cdots f_1(u(k-n_c)) \cdots f_p(u(k-1)) \cdots f_p(u(k-n_c)) \]
\[
g_1(z(k-1)) \cdots g_1(z(k-n_c)) \cdots g_q(z(k-1)) \cdots g_q(z(k-n_c)) \]^T \in \mathbb{R}^{(p+q)n_c}.
\]

To illustrate the NARMAX/I controller structure, let $f_1(u) = u$, $f_2(u) = u^2$, and $f_3(u) = u^3$. Then $\theta(k)$ and $\phi(k - 1)$ can be expressed as
\[
\theta(k) \triangleq [M_{11}(k) \cdots M_{1n_c}(k) M_{n_c+1}(k) \cdots M_{2n_c+1}(k) \cdots M_{3n_c}(k) N_{11}(k) \cdots N_{n_c}(k) \in \mathbb{R}^{n_c
\times (3n_c+l_x)}
\]
and
\[
\phi(k - 1) \triangleq [u(k-1) \cdots u(k-n_c) u^2(k-1) \cdots u^2(k-n_c) u^3(k-1) \cdots u^3(k-n_c) z(k-1) \cdots z(k-n_c) ]^T \in \mathbb{R}^{n_c(3n_c+l_y)}.
\]

To illustrate the NARMAX/O controller structure, let $g_1(z) = z$ and $g_2(z) = z^2$. Then $\theta(k)$ and $\phi(\phi(k - 1))$ can be expressed as
\[
\theta(k) \triangleq [M_{11}(k) \cdots M_{n_c}(k) N_{11}(k) \cdots N_{n_c}(k) N_{n_c+1}(k) \cdots N_{2n_c}(k) \in \mathbb{R}^{n_c
\times (n_c+2l_x)}
\]
and
\[
\phi(k - 1) \triangleq [u(k - 1) \cdots u(k - n_c) z(k - 1) \cdots z(k - n_c) z^2(k - 1) \cdots z^2(k - n_c)]^T \in \mathbb{R}^{n_c(n_c+2l_x)}.
\]

Next, let $d$ be a positive integer such that $\hat{V}(k - 1)$ contains $v(k - d)$ and define the cumulative cost function
\[
J_R(\theta, k) \triangleq \sum_{i=d+1}^{k} \lambda^{k-i}\|\phi^T(i - d - 1)\theta^T(k) - \nu^T(i - d)\|^2 + \lambda^{k}(\theta(k) - \theta_0)P_0^{-1}(\theta(k) - \theta_0)^T,
\] (19)
where \( \| \cdot \| \) is the Euclidean norm, and \( \lambda \in (0, 1] \) is the forgetting factor. Minimizing (19) yields
\[
\theta^T(k) = \theta^T(k - 1) + \beta(k)P(k - 1)\phi(k - d - 1) \cdot [\phi^T(k - d)P(k - 1)\phi(k - d - 1) + \lambda(k)]^{-1}
\cdot [\phi^T(k - d - 1)\theta^T(k - 1) - \hat{v}^T(k - d)],
\]
where \( \beta(k) \) is either zero or one. The error covariance is updated by
\[
P(k) = \beta(k)\lambda^{-1}P(k - 1) + [1 - \beta(k)]P(k - 1) - \beta(k)\lambda^{-1}P(k - 1)\phi(k - d - 1)
\cdot [\phi^T(k - d - 1)P(k - 1)\phi(k - d) + \lambda]^{-1} \cdot \phi^T(k - d - 1)P(k - 1).
\]
We initialize the error covariance matrix as \( P(0) = \alpha I_{3n_c} \), where \( \alpha > 0 \).

III.C. Auxiliary Nonlinearities and the Adaptive NARMAX Controller

To account for the presence of the input nonlinearity \( N \), the RCAC controller in Figure 2 uses two auxiliary nonlinearities.\(^{19} \) The auxiliary nonlinearity \( N_1 \) modifies \( u_c \) to obtain the regressor input \( u_r \), while the auxiliary nonlinearity \( N_2 \) modifies \( u_r \) to produce the Hammerstein plant input \( u \). The auxiliary nonlinearities \( N_1 \) and \( N_2 \) are chosen based on limited knowledge of the input nonlinearity \( N \), as described below.

III.C.1. Auxiliary Nonlinearity \( N_1 \)

Define the saturation function \( \text{sat}_a \) by
\[
N_1(u_c) = \text{sat}_a(u_c) = \begin{cases} 
-a, & \text{if } u_c < -a, \\
u_c, & \text{if } -a \leq u_c \leq a, \\
a, & \text{if } u_c > a,
\end{cases}
\]
where \( a > 0 \) is the saturation level. For minimum-phase plants, the auxiliary nonlinearity \( N_1 \) is not needed, and thus the saturation level \( a \) is chosen to be a large number. For NMP plants, the saturation level \( a \) is used to tune the transient behavior. In addition, the saturation level is chosen to provide the magnitude of the control input needed to follow the command \( r \). This level depends on the range of the input nonlinearity \( N \) as well as the gain of the transfer function \( G \) at frequencies in the spectra of \( r \).

III.C.2. Auxiliary Nonlinearity \( N_2 \)

To construct \( N_2 \), we assume that the intervals of monotonicity of the input nonlinearity \( N \) are known; no further modeling information about \( N \) is needed. Since the range of \( N_1 \) is \([-a, a]\), we need consider only...
\( u_r \in [-a, a] \). Therefore, let \( I_1, I_2, \ldots \) be intervals that partition the interval \([-a, a]\). If \( N \) is nondecreasing on \( I_i \), then \( N_2(u_r) \triangleq u_r \) for all \( u_r \in I_i \). Alternatively, if \( N \) is nonincreasing on \( I_i = (p_i, q_i) \), then \( N_2(u_r) \triangleq p_i + q_i - u_r \in I_i \) for all \( u_r \in I_i \). Finally, if \( N \) is constant on \( I_i \), then either choice can be used. Thus, \( N_2 \circ N \) is a piecewise-linear function that effectively replaces \( N \) by its mirror image on each interval within which \( N \) is nonincreasing. Let \( \mathcal{R}_a(f) \) denote the range of the function \( f \) with arguments in \([-a, a]\). Assume that \( N_2 \) is constructed by the above rule. Then the following statements hold:

i) \( N \circ N_2 \) is piecewise nondecreasing.

ii) \( \mathcal{R}_a(N \circ N_2) = \mathcal{R}_a(N) \).

Knowledge of only the intervals of monotonicity of \( N \) is needed to modify the controller output \( u_r \) so that \( N \circ N_2 \) is piecewise nondecreasing. For details, see.\(^{19}\)

**III.C.3. NARMAX/O**

To choose nonlinear function \( f_j \) for NARMAX/O controller

\[
\begin{align*}
    u(k) &= \sum_{j=1}^{p} \sum_{i=1}^{n_j} M_{ji}(k)f_{ji}(u(k-i)) + \sum_{j=1}^{q} \sum_{i=1}^{n_j} N_{ji}(k)z(k-i),
\end{align*}
\]

we assume that the interval of controller outputs \([u_{\text{min}}, u_{\text{max}}]\) needed to follow the command signal \( r \) is known and \( N \circ N_2 \) is piecewise nondecreasing. No further modeling information about \( N \) is required. The function \( f(u) \) is chosen to be one-to-one for \( u \in [u_{\text{min}}, u_{\text{max}}] \) and satisfies \( f(0) = 0 \) if \( 0 \in [u_{\text{min}}, u_{\text{max}}] \).

**IV. Numerical Examples**

Each example is constructed such that the first nonzero Markov parameter \( H_d = 1 \), where \( d \) is the relative degree of \( G \). RCAC generates a control signal \( u(k) \) that attempts to minimize the performance \( z(k) \) in the presence of the reference signal \( r \) and the input nonlinearity \( N \). We assume that measurements of \( z(k) \) are available for feedback; however, measurements of \( v = N(u) \) are not available. In all cases, we initialize the adaptive controller to zero, that is, \( \theta(0) = 0 \). We do not use a forgetting factor in this paper, that is, \( \lambda = 1 \) for all examples.

To illustrate the distortion reduction on the closed-loop command-following performance with Hammerstein RCAC controllers, we first simulate the Hammerstein plant with a linear RCAC controller. Following the same procedure, we simulate the Hammerstein plant using a NARMAX RCAC controller. Then, we compare the command-following performance \( z \) for both cases. In all simulations, we run the open-loop system for the first 100 time steps. Then, at \( k = 100 \), we turn the adaptation on, and let RCAC adapt the NARMAX controller in the presence of the unknown input nonlinearity \( N \).

**Example IV.1.** We consider the asymptotically stable, minimum-phase plant

\[
G(z) = \frac{(z - 0.5)(z - 0.9)}{(z - 0.7)(z - 0.5 - j0.5)(z - 0.5 + j0.5)},
\]

with the input nonlinearity

\[
N(u) = u^3.
\]

We consider the sinusoidal command \( r(k) = \sin(\theta_1 k) \), where \( \theta_1 = \pi/5 \) rad/sample. As shown in Figure 3(e), the input nonlinearity \( N \) is one-to-one and onto. We choose \( N_1(u_c) = \text{sat}_a(u_c) \), where \( a = 10 \) in (20). Since \( N \) is monotonically increasing for all \( u \in \mathbb{R} \), we choose \( N_2(u_r) = u_r \). Note that knowledge of only
the monotonicity of $N$ is used to choose $N_1$ and $N_2$. We consider the NARMAX/O controller structure. In particular, we choose $f_1(u) = u$, $f_2(u) = \sin(2u)$, $f_3(u) = \sin(0.5u)$, $f_4(u) = \sin(0.25u)$, and $f_5(u) = \sin(0.125u)$ for the NARMAX/O model. Furthermore, we let $n_c = 10$, $P_0 = 0.01 I_{s_n}$, $\eta_0 = 0.001$, and $\mathcal{K} = H_1$. Figure 3 (a) and (b) show the closed-loop response of command-following performance $z$ and $\log |z|$ with a linear controller structure, and (c) and (d) show the closed-loop response with a NARMAX/O controller structure. The command-following performance in (c) and (d) are improved by approximately a two orders of magnitude compared with the performance in (a) and (b) at $k = 2000$ time step. The NARMAX controller provides faster convergence compared with the linear controller structure. Figure 3(f) shows the auxiliary nonlinearity $N_2(u_c(k))$. Finally, Figures 3(g) and (h) show the time history of the controller output $u$ and the controller gain vector $\theta$.

Example IV.2. We consider the linear plant (22) with the input nonlinearity $N(u) = u^3 + 5$ and note that $N(0) \neq 0$. We choose $f_1(u) = u$ and $f_2(u) = \sin(0.25u)$ for the NARMAX/O model. We consider the same sinusoidal command $r(k) = \sin(\theta_1 k)$, where $\theta_1 = \pi/5$ rad/sample and apply the same control parameters as in Example IV.1. We let the simulation run for 12,000 time steps, and Figure 4(a) shows the closed-loop response of $\log |z|$ with the linear controller structure (dotted line) and NARMAX/O structure (solid line). NARMAX controller improves the steady-state performance.

Next, we further investigate the effect of the condition $N(0) \neq 0$. Consider the linear plant (22) with the input nonlinearity $N(u) = u^3 + \varepsilon$, where $\varepsilon \in \mathbb{R}$. Furthermore, we consider same sinusoidal command $r(k) = \sin(\theta_1 k)$, where $\theta_1 = \pi/5$ rad/sample, and apply the same NARMAX/O controller structure and controller parameters as in the last example. Figure 4(b) shows that the steady state performance of linear controller versus the NARMAX controller for various $\varepsilon$. Note that the NARMAX controller compensates for $N(0) \neq 0$.

Example IV.3. We consider the asymptotically stable, nonminimum-phase plant

$$G(z) = \frac{z - 1.5}{(z - 0.8)(z - 0.6)},$$

with the input nonlinearity

$$N(u) = -0.8 \tanh(u).$$

We consider the two-tone sinusoidal command $r(k) = 0.5 \sin(\theta_1 k) + 0.5 \sin(\theta_2 k)$, where $\theta_1 = \pi/5$ rad/sample and $\theta_2 = \pi/2$ rad/sample. As shown in Figure 5(e), the input nonlinearity $N_H$ is one-to-one but not onto. We choose $N_1(u_c) = \text{sat}_a(u_c)$, where $a = 2$ in (20). Since $N$ is monotonically decreasing for all $u \in \mathbb{R}$, we choose $N_2(u_c) = -u_c$. Note that knowledge of only the monotonicity of $N$ is used to choose $N_1$ and $N_2$. We consider the NARMAX/O controller structure. In particular, we choose $f_1(u) = u$, $f_2(u) = u^3$, and $f_3(u) = u^5$ for the NARMAX/O model. Furthermore, we let $n_c = 10$, $P_0 = 0.01 I_{s_n}$, $\eta_0 = 0.8$, and $\mathcal{K} = H_1$. Figures 5(a) and (b) show the closed-loop response of command-following performance $z$ and $\log |z|$ with a linear controller structure, and (c) and (d) show the closed-loop response with a NARMAX/O controller structure. The command-following performance in (c) and (d) are improved by approximately a one order of magnitude compared with the performance in (a) and (b). Figure 5(f) shows the auxiliary nonlinearity $N_2(u_c(k))$. Finally, Figures 5(g) and (h) show the time history of the controller output $u$ and the controller gain vector $\theta$.

Example IV.4. We consider the asymptotically stable, minimum-phase plant

$$G(z) = \frac{(z - 0.5)(z - 0.9)}{(z - 0.7)(z - 0.5 - j0.5)(z - 0.5 + j0.5)},$$

with the input nonlinearity

$$N_H(u) = \cos(u).$$

We consider the sinusoidal command $r(k) = \sin(\theta_1 k)$, where $\theta_1 = \pi/5$ rad/sample. As shown in Figure 6(e), the input nonlinearity $N$ is neither one-to-one nor onto. We choose $N_1(u_c) = \text{sat}_a(u_c)$, where $a = 4$
Figure 3. Example IV.1. Closed-loop response of the plant $G$ given by (22). The system runs open loop for 100 time steps, and the adaptive controller is turned on at $k = 100$ with auxiliary nonlinearity $N_1$ and $N_2$ based on the knowledge the monotonicity of $N$. The plant output $y$ follows the command $r(k)$. We choose $f_1(u) = u$, $f_2(u) = \sin(2u)$, $f_3(u) = \sin(u)$, $f_4(u) = \sin(0.5u)$, $f_5(u) = \sin(0.25u)$, and $f_6(u) = \sin(0.125u)$ for the NARMAX/O model. The NARMAX controller provides faster convergence compared with the linear RCAC, and (a) and (b) show the closed-loop response of command-following performance $z$ and $\log|z|$ with a linear controller structure. The command-following performance in (c) and (d) are improved by approximately a two orders of magnitude compared with the performance in (a) and (b) at $k = 2000$ time step.

in (20). Since $N$ is monotonically increasing for all $u \in (2n\pi - \pi, 2n\pi), n \in \mathbb{Z}$, we choose $N_2(u) = u$, and
Figure 4. Example IV.2. (a) shows the closed-loop response to the command signal \( r(k) = \sin(\theta_1 k) \), where \( \theta_1 = \pi/5 \) rad/sample with the nonlinearities \( N(u) = u^3 + 5 \) and the linear plant (22) with the linear controller structure (solid line) and NARMAX/O controller (dotted line). NARMAX controller improves the steady state performance with input nonlinearity satisfying \( N(0) \neq 0 \). (b) shows that the steady state performance of linear controller versus the NARMAX controller for various \( \varepsilon \). Note that \( |z_{ss}| = 0.707 \) is the performance error for the open-loop system and the command-following performance distortion is compensated by the NARMAX controller with the input nonlinearity satisfying \( N(0) = \varepsilon \).

since \( N \) is monotonically decreasing for all \( u \in (2n\pi, 2n\pi + \pi), n \in \mathbb{Z} \), we choose \( N_1(u_c) = -u_c + (4n + 1)\pi \). Note that knowledge of only the monotonicity of \( N \) is used to choose \( N_1 \) and \( N_2 \). We consider the NARMAX/IO controller structure. In particular, we choose \( g_1(z) = z, g_2(z) = \sin(2z), g_3(z) = \sin(z), g_4(z) = \sin(0.5z), f_1(u) = u, f_2(u) = \sin(2u), f_3(u) = \sin(u), \) and \( f_4(u) = \sin(0.5u) \) for the NARMAX/IO controller. Furthermore, we let \( n_c = 10, P_0 = 0.1I_{14n_c}, \eta_0 = 0.02, \) and \( K = H_I \). Figures 6 (a) and (b) show the closed-loop response with a linear RCAC, and (c) and (d) show the closed-loop response with a NARMAX RCAC controller. The command-following distortion in (c) and (d) are approximately 20% smaller compared with the performance distortion in (a) and (b). Figure 6(f) shows the auxiliary nonlinearity \( N_2(u_r(k)) \). Figures 6(g) and (h) show the time history of the controller output \( u \) and the controller gain vector \( \theta \). Finally, Figure 6(i) shows the time history of the control \( u_r \) and the plant input \( v \) and \( v \) is piecewise increasing versus \( u_r \).
Figure 5. Example IV.3. Closed-loop response of the plant $G$ given by (24). The system runs open loop for 500 time steps, and the adaptive controller is turned on at $k = 500$ with input nonlinearity $N_1$ and $N_2$ based on the knowledge the monotonicity of $N$. The plant output $y_0$ follows the command $r(k)$. We choose $f_1(u) = u$, $f_2(u) = u^3$, and $f_3(u) = u^5$ for the NARMAX/O model. Figure 5 (a) and (b) show the closed-loop response of command-following performance $z$ and $\log|z|$ with a linear controller structure. The command-following performance in (c) and (d) are improved by approximately a one order of magnitude compared with the performance in (a) and (b).

V. Conclusions

Retrospective cost adaptive control (RCAC) with a NARMAX control structure was applied to command following for Hammerstein systems. RCAC was used with limited modeling information. In particular,
Figure 6. Example IV.4. Closed-loop response of the plant \( G \) given by (26). The system runs open loop for 500 time steps, and the adaptive controller is turned on at \( k = 500 \) with input nonlinearity \( N_1 \) and \( N_2 \) based on the knowledge the monotonicity of \( N \). The plant output \( y_0 \) follows the command \( r(k) \). We choose \( g_1(z) = z, g_2(z) = \sin(2z), g_3(z) = \sin(z), g_4(z) = \sin(0.5z) \), \( f_1(u) = u, f_2(u) = \sin(2u), f_3(u) = \sin(u), \) and \( f_4(u) = \sin(0.5u) \) for the NARMAX/IO controller. Figures 6(a) and (b) show the closed-loop response with a linear controller structure. The command-following performance distortion in (c) and (d) are approximately 20% smaller compared with the performance distortion in (a) and (b) using the NARMAX/IO controller structure.
RCAC uses knowledge of the first nonzero Markov parameter of the linear system. To handle the effect of the input nonlinearity, RCAC was augmented by auxiliary nonlinearities chosen based on the monotonicity properties of the input nonlinearity. We numerically demonstrated that RCAC with a NARMAX controller structure can improve the command-following performance for the Hammerstein systems over the linear controller structure for providing fast convergence and compensating performance distortion for $N(0) \neq 0$.

Future research will focus on choosing NARMAX structures for RCAC based on limited knowledge of the uncertain Hammerstein nonlinearities.
